SAGE was founded in 1965 by Sara Miller McCune to support the dissemination of usable knowledge by publishing innovative and high-quality research and teaching content. Today, we publish over 900 journals, including those of more than 400 learned societies, more than 800 new books per year, and a growing range of library products including archives, data, case studies, reports, and video. SAGE remains majority-owned by our founder, and after Sara's lifetime will become owned by a charitable trust that secures our continued independence.

About the Editors

Donna Couchenour is professor emerita of early childhood teacher education at Shippensburg University of Pennsylvania where she has served as early childhood chair for both undergraduate and graduate programs. She received her bachelor's degree in elementary and early childhood education from Clarion University of Pennsylvania, her master's degree in child development from West Virginia University, and her Ph.D. in human development and family studies from The Ohio State University. Couchenour has been a faculty member in early childhood teacher education for more than 30 years and has been employed as a laboratory school director at both West Virginia University and Oklahoma State University, as a Head Start teacher and director, and as a military child care training and curriculum specialist. She has taught courses on child development, the early childhood education profession, curriculum and assessment, and partnerships for family engagement and has supervised internship experiences at various student levels. With her coeditor of this work, she has published three books: *Families, Schools and Communities: Together for Young Children*, currently in its fifth edition; *Healthy Sexuality Development in Young Children*; and *In the Field: Guided Field Assignments and Readings in Early Childhood Education*. Couchenour was selected and has served as an early childhood teacher preparation program reviewer and audit team member for the National Association for the Education of Young Children (NAEYC) and as a Board of Examiners member for the National Council for the Accreditation of Teacher Education (NCATE, now Council for the Accreditation of Educator Preparation [CAEP]).

J. Kent Chrisman is professor of early childhood education at Shippensburg University of Pennsylvania. He received his bachelor's degree in psychology from Hendrix College, his master's degree in early childhood education from George Peabody College for Teachers, and his Ed.D. in educational supervision from the University of Louisville. Chrisman has been a faculty member in early childhood teacher education for more than 30 years as well as serving as a laboratory school director at Stephen F. Austin State University in Texas (infants through first grade) and in a public school partnership laboratory school in Pennsylvania (PreK–6). He has taught courses in curriculum, child development, and partnerships for family engagement and has supervised internship experiences at various student levels. With his coeditor of this work, he has published three books: *Families, Schools and Communities: Together for Young Children*, currently in its fifth edition; *Healthy Sexuality Development in Young Children*; and *In the Field: Guided Field Assignments and Readings in Early Childhood Education*. In addition, he is a coauthor of *Teaching Young Children Mathematics* and *Young Children and Social Studies*. As Pennsylvania made strides to strengthen early childhood teacher preparation, Chrisman was invited to participate as a member of a statewide committee that recommended standards and programming to the state board of education. Appointed by the governor, he also served as a member of the Pennsylvania Early Learning Council. He has also served as president of the Pennsylvania Association of Early Childhood Teacher Educators and as president of three state affiliates of the National Association for the Education of Young Children in Texas, Kentucky, and Pennsylvania.

Introduction

The Field

Early childhood education refers to the education of all young children, typically and atypically developing, from birth through 8 years of age. Early childhood educators may have experience and professional preparation with this entire age range, or they may have specialized experiences with infants and toddlers (birth–3 years), preschoolers (3–5 years), kindergartners (5–6 years), or primary grade-age children (6–8 years). Their expertise may be with typically developing children, children with special needs, or inclusive programming. Goals for early childhood educators include providing education that is developmentally appropriate for individual children and facilitating effective family engagement that supports children’s optimal development.

The field of early childhood education has diverse roots and continues to be multidisciplinary in nature in that research and theory from several fields have been integrated into the study of teaching young children. To understand historical foundations of early education in the United States, one must look to child development, educational theory and practice, family science, social work, and neuroscience. Even though all states in the union (as it existed then) had public schools by 1870, it was not until after the mid-20th century that kindergarten became more common in public elementary school designs. Early public kindergarten programs were almost universally part-day, but now many full-day kindergarten programs exist.

As an aspect of President Lyndon Johnson’s War on Poverty, Head Start programs were implemented for the first time in 1965. Although not without critics, Head Start is widely viewed as a

successful comprehensive early education and family support program for low-income families. Federal and state funding continues for Head Start even though there have been frequent threats to severely or totally cut budgets. Although state-funded preschool programs for children ages 3 to 5 years are appearing in many states today, universal preschool remains a pipe dream for many early education policy experts. Funding and criteria vary by state.

Often overlooked as a stream of early childhood education, child care programs have steadily grown in number since the 1970s when the economy and the women’s movement led to many mothers working outside the home. Most child care centers remain privately owned, but many states now offer financial support and professional development for those who participate in quality improvement programs. Child care centers typically offer full-day care for children from 6 weeks old through prekindergarten age.

Although this encyclopedia defines the early childhood years as birth through 8 years of age, or third grade, some sources and policies continue to define early childhood education as programs for children from birth through 5 years of age. This has been a rather serious source of contention since traditionally public schools have included first through sixth (and earlier, first through eighth) grades as elementary education. In recent decades, teacher certification offered by states often includes kindergarten through sixth grade with the licensure to teach elementary school. In the late 1960s and early 1970s many states created early childhood education licenses, but there was often an overlap with elementary licensure in pre-kindergarten through third grade. School boards,

principals, and superintendents often saw those with the early childhood education licenses as less desirable hires because administrators would have greater limitations in moving these teachers to other grade levels in order to meet each year's enrollment needs.

Research that has examined effects of early childhood teacher licensure on young children's development and learning is difficult in that licensure programs vary in emphasis (e.g., developmental versus subject matter) and quality. Individual teacher candidate variables are difficult to assess as well. The National Association for the Education of Young Children has created a position statement with standards that are necessary for early childhood teacher preparation programs. This position statement is based on existing evidence for preparing teachers of young children, from birth through third grade. Additionally, the National Association of Early Childhood Teacher Educators (NAECTE) has produced a position statement regarding the need for teachers of children ages 8 years and younger to earn an early childhood teaching license, saying, "If children are to thrive in school and meet current expectations for achievement they need teachers who have specialized knowledge of child development and best practices in early childhood education" (NAECTE, p. 2). Although there is strong confidence within the field about how best to prepare teachers of young children, political and managerial factors in elementary school settings too frequently lead to overlooking the importance of professional preparation specific to early education in hiring processes. Early childhood teacher preparation specifically includes knowledge of child development for planning age-appropriate curriculum and instruction and for guiding children's behavior, knowledge about the importance of reciprocal partnerships with families, and ability to assist children and families as they transition from early childhood settings to elementary schools.

Currently, a movement has been garnering attention based on strong evidence that points to the importance of a prekindergarten through third grade alignment of curriculum goals and assessment. In brief, positive child outcomes from

high-quality preschool programs have been shown to have greater longevity when talented and credentialed early childhood teachers who have the ability to create aligned systems are hired to teach young children through the third grade.

Because early childhood includes education for all children in the birth through 8 years age range, programs of early intervention are also included in this encyclopedia. When children are assessed as having one or more disabilities, the most effective interventions occur early and are both intensive and extensive in nature.

In all early childhood education formats, family engagement is an essential element for successful child outcomes. Strong early childhood professional preparation programs include information about the importance of creating reciprocal partnerships with children's family members as well as strategies and experiences for engaging families in their children's learning. Successful early childhood educators do not see family engagement as optional, but rather as an essential component for optimal outcomes for each child.

As pointed out in the 2015 report from the Institute of Medicine (IOM) and National Research Council (NRC) at the National Academy of Sciences, *Transforming the Workforce for Children Birth Through Age 8: A Unifying Foundation*, our current understanding of providing the best education for young children from birth through age 8 requires immediate attention to professional preparation of early childhood educators and leaders. The report states: "For too long, the nation has been making do with the systems and policies that *are* rather than envisioning the systems and policies that are *needed*, and committing to the strategies necessary to achieve them" (IOM & NRC, p. 15). To support early childhood education as a discipline, professionals must be educated with the content and pedagogical knowledge and skills necessary for teaching all young children and especially those who are most vulnerable.

Topics presented in this encyclopedia include, but are not limited to, the following:

Assessment—limitations of assessment, authentic assessment, checklists and rating scales, developmental

assessment, developmental screening instruments, intellectual assessment, interpreting assessment data, mental health assessments, Classroom Assessment Scoring System (CLASS)

Associations—National Association for the Education of Young Children, National Center for Children in Poverty, National Head Start Association, National Institute for Early Education Research, Ounce of Prevention Fund, Resources for Infant Educators, ZERO TO THREE

Child Care—Family child care, center-based care, child care policy and practice, child care quality and young children's behavior, military child development centers

Child Development—Typical development, atypical development, brain development, child care assistance and child development, child development and early childhood education, determinants of child development, early number representation development, executive functioning, home-based early childhood education, neuroscience and early education

Child Development–Cognition—imagination, multiple intelligences, pretense, reasoning and problem solving, spatial development, social class effects on development and learning, theory of mind, thinking

Child Development–Language/Literacy—language development, language disabilities, language diversity, literacy, literacy assessment, literacy-enhanced props, oral language development, speech development, vocabulary

Child Development–Physical/Motor—healthy choices and young children, physical education, sensory development, sensory integration, sexuality development, sleep

Child Development–Social/Emotional—young children's understanding of grief and loss, guiding behavior, guidance with girls, initiative and industry, trust, autonomy, mental health services, mindfulness,

moral development, mutual regulation model, prosocial behavior, shyness in young children

Collaboration—transitioning, Oklahoma's quality initiatives, community partnerships, community–university partnerships, business partnerships, caring communities

Curriculum—art, arts integration, approaches to early mathematics instruction, Bank Street, children's literature, children's writing, the work of Sylvia Ashton-Warner, Common Core State Standards, constructivist curriculum, The Creative Curriculum, curriculum and early childhood education, emergent curriculum, family engagement in curriculum, HighScope, infant and toddler programming, infant signing, integrated curriculum, key words, children's understanding of measurement, Montessori programs and environments, movement education, music, the project approach, reading, the Reggio Emilia approach, science, social studies topics, standards, storytelling and story acting, Tools of the Mind, theater

Diversity—inequality from birth, family structure diversity, ethnic differences and families, equity and equality in early childhood, dual language learners, strategies for dual language learners, diversity in early childhood education, development of prejudice, cultural competence, bias, professional development for diversity

Early Intervention—recommended early intervention practice guidelines, personnel preparation for early intervention, physical disabilities, home-based early intervention practices, home visitation with mothers and infants and children, legal basis for early intervention, early childhood inclusion, developmental disabilities, autism spectrum disorder, attention-deficit/hyperactivity disorder, assistive technology in early intervention

Environments—accreditation, challenging and supportive climates, child development laboratory schools, Comer schools, community schools, healthy environments for social-emotional development, infant rooms, kindergarten environments,

looping, multiage spaces, outdoor play spaces, preschool rooms, toddler rooms, primary grade learning spaces

Families—religion and families, refugee children, sibling relationships, substance abuse and addiction, teen pregnancy and parenting, transition to parenthood, violence in families, work and families, parenting effects on child development, parents as teachers, parenting support and education, family life education, mothers, fathers, grandparent roles, family-centered practices

Play—play and early childhood education, guided play, importance of free play, rough and tumble play, economic differences in play, cultural variations in play, commercialism, child-initiated play, recess, noncurricular play

Policy and Advocacy—child care policy and practice, early childhood education and crime, data-based child advocacy, early childhood education systems, early childhood special education, effective advocacy practices, high-stakes standards-based accountability reform, history of early childhood education policy

The Profession of Early Childhood Education—early childhood education, play and early childhood education, preservice teacher preparation, pedagogical knowledge, content knowledge, accountability in early care and education, conceptual framework for teacher preparation programs, coaching, defining early childhood education, developmentally appropriate practice

Teaching and Learning—approaches to learning, classroom processes, cooperative learning, differentiated instruction and assessment, early childhood science experiences, engaging conversation, grade retention, inquiry-based learning, kindergarten, primary grades, the National Early Literacy Panel, prekindergarten

Theories and Models—anti-bias education theory, behavioral theory, bioecological theory, cognitive developmental theory, constructivism, critical the-

ory, maturational theory, models, sociocultural theory, stage theories, psychosexual theory, psychosocial theory

The SAGE Encyclopedia of Contemporary Early Childhood Education contains 10 anchor essays that are lengthier, providing readers with more depth than other entries. In each case, a highly regarded expert in the field was selected to write the anchor. In alphabetical order, the anchor entries and authors are as follows:

Child Development and Early Childhood Education
Martha Buell

Curriculum and Early Childhood Education
Lawrence J. Schweinhart

Developmentally Appropriate Practice
Heather Biggar Tomlinson

Early Childhood Education
Anne Douglass

Early Childhood Teacher Education
Tracy E. Collins

Early Intervention

Ethics in Early Childhood Education
Stephanie Feeney and Nancy K. Freeman

Kindergarten
Daphna Bassok and Tashia Abry

Play and Early Childhood Education
James E. Johnson

Policy and Early Childhood Education
Holly S. Schindler

Rationale for the Encyclopedia

Whereas some programs and various aspects of high-quality early childhood education have been present for well over two centuries, in the United States today, awareness of early childhood education as a distinct field of study and teacher preparation is increasing. Yet, traditional boundaries remain a barrier in both professional preparation and school formats. This encyclopedia was created

with an emphasis on early childhood education as a multidisciplinary field based on theoretical, empirical, and practical evidence that supports the birth through 8 years definition.

Designed as a reference to introduce essential components of early childhood education to undergraduate students and graduate students in all licensure areas of teacher education and in other school professional preparation programs and to practicing teachers and other school professionals who wish to gain current information, this resource provides access to a basic level of understanding. Further, because education is funded and regulated by numerous federal, state, and local agencies, this encyclopedia provides expert information to policy makers.

Content and Organization

As this encyclopedia was designed by the editors and editorial board members, efforts were made to be all-inclusive of topics currently studied by early childhood education professionals. We hope that we have met the challenge of inclusiveness without being overly redundant.

A reader's guide is provided to assist readers in navigating the encyclopedia. A list of entries in alphabetical order, along with cross-references, is provided.

How the Encyclopedia Was Created

The SAGE Encyclopedia of Contemporary Early Childhood Education was developed through these steps:

Step 1—The general editors invited Jennifer Pyles to serve as managing editor for this work. Together, they identified and contacted leading early childhood education experts in the United States to serve on the editorial board with attention given to balancing board members' areas of expertise (e.g., curriculum, child development, families, and play).

Step 2—A master list of topics was created by the general editors and managing editor, beginning with the list that was sent to SAGE in the prospectus for this project. In doing this, we examined

major textbooks and journals for topics. We also reviewed national standards for teacher preparation to ensure that topics related to child development, family engagement, assessment, teaching and learning, curriculum, professionalism, and fieldwork/praxis were included.

Step 3—Contributors were identified by the editors and editorial board members. We also searched for authors for particular entries through Google Scholar. As authors responded, we sometimes changed the terminology of entries to better align with current trending topics. Although we had a high rate of acceptances, we found that many of our colleagues have commitments that prohibit or limit them from accepting new invitations for writing projects. Early childhood education faculty members, in particular, seem to have very heavy teaching and research loads, yet so many were willing to commit to this "gift" for the field. Contributors run the gamut of venerable experts to up-and-coming scholars.

Step 4—Authors of entries were given basic guidelines and instructions from SAGE and also guidelines for accessing the SAGE Reference Tracking (SRT) system. The invitation letter explained the need for thoroughness of the topic along with the importance of using accessible language. Our managing editor and SAGE staff were responsive to authors as they posed questions and made suggestions.

Step 5—The general editors reviewed all entries and requested content revisions as necessary. After final review, editors sent final drafts to SAGE for transmission for publication. Authors were informed of the status of their submissions throughout the process.

Step 6—The general editors created a list of annotated websites and associations for the back matter of the encyclopedia.

Acknowledgments

This encyclopedia has been a tremendous undertaking and would not have been possible without support and contributions from many extraordinary people! The general editors sent a prospectus

to SAGE and received huge support from Jim Brace-Thompson as we navigated the acceptance tasks. As soon as we received the contract, we invited Jennifer Pyles and Annie Papero to serve as managing editors. Although Annie worked with us only a short time due to a change in her professional goals and relocation, her enthusiasm and knowledge base are reflected in the end product. Jennifer picked up the entire project and worked diligently to send out invitations and communicate with sensitive responses to contributors while continually checking in with the general editors and SAGE staff. Without Jennifer's talents and efforts, this encyclopedia would not be the outstanding resource that it is!

Early in our work, Shirin Parsavand was assigned as our developmental editor. She helped us in defining this work as well as in editing the entries. We value Shirin's suggestions and experience in all of the technical aspects of our work on this encyclopedia. We were also fortunate to have Anna Villaseñor and Leticia Gutierrez as support from SAGE.

Our editorial board members were essential with their assistance to ensure that we would have an inclusive and balanced reference work. Many of them contributed one or more outstanding entries and made recommendations for topics and authors in their areas of expertise. Alphabetically, board members are Nancy Barbour, Harriet Dichter, Jo Ann M. Farver, Stephanie Feeney, Marcy Guddemi, James E. Johnson, Marjorie Kostelnik, Lawrence J. Schweinhart, and Heather Biggar Tomlinson. We were saddened to learn of Kevin Swick's passing during the summer of 2014. He was instrumental in assisting with content during

the early conceptualization of this work, particularly in the area of family engagement.

We can never offer enough gratitude to our gracious contributors. They provided us with current content written in accessible language and met deadlines that were sometimes nearly impossible given their other commitments. On a personal note, we were so fortunate to have friends and family who encouraged and supported us in the completion of this project.

ABECEDARIAN PROJECT

The extent to which the life course of intellectual development is positively modifiable by systematic interventions is a topic of general interest, with more than a half-century of scientific inquiry with strong public policy implications. Systematic public education has been the most direct policy response to this topic. Middle- and upper-class families in the United States spend billions of dollars to provide their children with good education as a pathway to adult success. The most extensive scientific research, however, about the power of education to change intellectual development has been conducted with children from poor and undereducated families who are at elevated risk for lack of school readiness, subsequent poor academic performance, and a long list of social and economic shortcomings. This entry describes the creation, conduct, and results of one pioneering experimental educational program for disadvantaged children conducted from birth to 8 years of age—the Abecedarian Project.

The experimental treatment was named the Abecedarian educational approach and focused on increasing children's kindergarten readiness and early school performance in reading, mathematics, and other academic skills. This entry summarizes findings showing that the Abecedarian educational approach improved participants' intellectual development and kindergarten readiness. The

Abecedarian educational approach has also been found to strengthen performance in reading and mathematics, with the largest benefits realized when the first five years of educational intervention are combined with a kindergarten through second grade (K–2) intervention. Follow-up research on participants and comparison students through age 35 shows that the Abecedarian educational approach leads to reduced grade retention, special education placement, drug use, depression, and welfare dependence as well as a greater likelihood of attending and graduating from college and having better adult health. Independently analyzed data suggest a greater than 3:1 return on investment up to early adulthood.

Building on a series of basic laboratory studies on early infant learning, summarized by John Watson and Craig Ramey in 1972, the Abecedarian Project began in 1971 with a 1-year pilot program and fully launched in 1972. The Abecedarian Project began as the first, and still only, two-stage randomized controlled trial (RCT) of the effects of early childhood education in the first 8 years of life. The central research question was: To what extent can providing high-quality early education to children from extremely impoverished and undereducated homes *prevent* intellectual disabilities, *promote* cognitive and positive social outcomes, and *improve* lifelong health and well-being?

Phase 1 randomly assigned infants to receive 5 continuous years of a theory-guided early educational program or to a control group. Both groups

Figure 1 Two-Phase Design of Abecedarian Project

Source: Adapted from Figure 2, Design of Abecedarian Project, p. 7. Ramey, C. T., Campbell, F. A., Burchinal, M., Skinner, M. L., Gardner, D. M., & Ramey, S. L. (2000). Persistent effects of early childhood education on high-risk children and their mothers. *Applied Developmental Science*, 4, 2-14.

received health, social, and nutritional supports. Phase 2 then randomly divided each of the phase 1 groups into two new groups—one received a school-age supplementary program from kindergarten through Grade 2, whereas the other did not. Figure 1 shows the overall research design and the primary follow-up occasions.

Scientific and Educational Contexts

Children who live in poverty disproportionately show intellectual disabilities compared to the general population. These intellectual disabilities have many causes and correlates, but frequently no identifiable biological causes can be found for the disabilities. In 1961, J. McVicker Hunt in his landmark book, *Intelligence and Experience*, proposed that the low quality and amounts of early learning experiences for children from intergenerationally poor families were an important cause of their subsequent low

level of intellectual performance. The Abecedarian Project built upon this broad hypothesis and the infant learning studies alluded to earlier with further specification that the following types of early experiences are crucial to support healthy intellectual development and school achievement: (a) responsive caregiving from adults; (b) conversational and informative language with caring adults; (c) exposure to books and warm conversational reading beginning in early infancy; and (d) an individually paced comprehensive educational curriculum within a child development center that was designed to be developmentally supportive, positive, and fun-filled. These types of experiences were systematically infused into more than 500 specially created and evaluated activities that comprise the 5-year Abecedarian educational curriculum, which includes these activities that were referred to as “learnin-games” and have been published, in part, in multiple formats and languages over the past four decades.

Cultural and Social Context

The Abecedarian Project took place in Chapel Hill, North Carolina, a fast-growing southern university town that, although generally socially liberal, did not fully racially integrate its public school system until 1968—14 years after the *Brown v. Board of Education* Supreme Court decision that ruled racially segregated school systems were inherently unequal. From 1970 to 2010, the town grew from roughly 26,000 to 57,000 because of university expansion, the growth of the burgeoning nearby Research Triangle Park, and an increase in relatively affluent retirees. Chapel Hill is contiguous with Carrboro, a town of approximately 20,000. The two towns share a school system. In 1972, when the study began, there were 33 separate social, housing, health, and welfare programs designed and staffed to assist economically disadvantaged families. Thus, the town and school systems were dedicated to a vigorous programmatic approach to improving the lives of disadvantaged families and their children.

Unemployment in the Chapel Hill/Carrboro geographic area was typically below 3% and the towns were buffered to a great extent from negative macroeconomic trends. The Chapel Hill/Carrboro area had an African American population of approximately 10%. Although some African Americans in Chapel Hill/Carrboro were affluent and highly educated, the vast majority were poor and undereducated. The Chapel Hill/Carrboro area was generally affluent and highly educated, with the university, its associated hospitals and clinics, and city and regional government being the major employers.

Steps to Creating Abecedarian Program

Recruitment and Enrollment

Pregnant women were screened through prenatal clinics, social service agencies, and hospital nurseries using a weighted 13-item high-risk index (shown in Table 1). Families that received a high-risk index score above 11 were invited to participate and told about the random assignment to different treatment groups. Of the 111 enrolled

families, 98% were African American and 2% were non-Hispanic White. The majority (76%) were female-headed households, and 66% of the mothers had educational levels below high school graduation. The mean IQ of mothers was approximately 80, 20 points below the average score of 100.

Shortly after birth, infants were randomly assigned to the early childhood educational treatment with 57 participants or control group with 54 participants. At entry into kindergarten (on average, at age 5), children were randomized again to a school-age educational program for the first three school years, from kindergarten through the summer after Grade 2. Thus, the participants' exposure to early childhood intervention ranged from a high of 8 years (combining the first five years of early childhood education and the primary grades), to 5 years in early childhood only, to 3 years in the primary grades only, to no systematic educational intervention. By age 5, the number of participating children was 105 (4 children died, 1 was withdrawn by the mother, and 1 proved ineligible because of a biological impairment not detected at birth).

Over the first 35 years, sample attrition remained at less than 10%—yielding high cohort maintenance that minimizes potential bias in the results. Further details, study design, and participant characteristics are included in the 2012 book by Craig Ramey, Joseph Sparling, and Sharon Ramey titled *Abecedarian: The Ideas, the Approach, and the Findings*.

Creating the Abecedarian Child Development Center

The Abecedarian educational program was delivered in a new building of the Frank Porter Graham Child Development Center (now Institute) at the University of North Carolina at Chapel Hill. Located away from the main campus and on the grounds of a new elementary school, the building afforded a generally “open” interior architecture for newly designed classrooms and educational spaces. Teachers and research staff were recruited and trained to deliver the planned educational program.

Note: Criterion for inclusion in high-risk sample was a score of more than 11.

Establishing the Educational Treatment and Control Conditions

To test the power of early childhood education to improve school readiness, it was important to control other influences already known, or strongly suspected, to be important for normal child development. Thus, children in both treatment and control groups were provided with free or reduced-cost medical care, nutritional supplements, and family support social services during the first five years of life. Mothers and children in both groups used these adjunct services at equally high rates. This design feature was to emphasize that the primary difference between the groups was the 5 years of the Abecedarian educational program, beginning when infants were 6 weeks to 3 months of age (in an era when infant day care was rare). The program was provided on 5 weekdays from 7:30 a.m. to 5:30 p.m. for 50 weeks each year.

To ensure full participation, transportation for all children was provided via specially equipped vans staffed with qualified drivers and center teachers or assistant teachers. Monthly parent meetings were held to engage and educate parents, as well to offer social support and meals. Teachers typically had bachelor-level degrees or higher, and assistant teachers had taken some college classes. Both teachers and assistant teachers participated in extensive preservice and in-service professional development on a weekly basis. Table 2 summarizes key components of the treatments given to the preschool educational and control groups. Unlike other studies of early childhood education that offered no extra supports to the control group, the Abecedarian Project focused on providing a stringent scientific test of the hypothesis that a systematic, high-intensity, and high-quality early childhood education program per se would positively impact children's intellectual and academic outcomes.

Creating the Abecedarian Curriculum

The educational curriculum was developed by a curriculum development team in conjunction with the research staff. The comprehensive birth to age 5 educational program focused on the following domains of development: language and

communication skills, social and emotional skills, cognitive skills, and motor and coordination functionality. The Abecedarian approach explicitly incorporated the following features in the curriculum and everyday exchanges (that were labeled as learning sets) between adults and children and among peers:

- Using adults as resources
- Allowing children to control aspects of their immediate environment
- Promoting use of both expressive and receptive language extensively
- Detaching self from caregiving adults and exploring independently
- Exhibiting sustained attention behavior
- Responding frequently with positive approach to new objects or persons
- Adapting and adjusting well to changes in environment
- Executing multi-step activities
- Anticipating consequences
- Generating specific instances of an educational concept by guidance of a general rule

Establishing a Multidisciplinary Research Team

Because the Abecedarian approach was an innovative and intensive scientific probe into human malleability using an RCT design, it required an interdisciplinary team to be comprehensive in its orientation and vigilant about potentially harmful side effects. The Abecedarian multidisciplinary team included curriculum developers, teachers, assistant teachers, home visitors, social workers, pediatricians, nurses, nurse practitioners, developmental and clinical psychologists, special educators, and linguists, as well as postdoctoral fellows and graduate students. The teachers and assistant teachers participated in professional development activities on a preservice and weekly in-service basis. Extensive data about children's activities in the preschool and their health and biological functioning (e.g., growth, infections) were collected, analyzed, disseminated, and discussed. When detected, health or behavioral problems were addressed in a timely manner for children in both treatment groups. Multiple methods of

(2000). Persistent effects of early childhood education on high-risk children and their mothers. *Applied Developmental Science*, 4, 2–14.

Note: NAEYC = National Association for the Education of Young Children.

observation and daily documentation were used to monitor adherence to the Abecedarian educational protocol and to prevent “program drift.” When needed, corrective actions were taken.

Phase 2: The Kindergarten to Second Grade (K–2) Home/School Resource Program and Summer Camp Programs

Rationale

As the Abecedarian Home/School Resource K–2 Program was being developed, surveys and focus groups with parents and elementary school teachers were conducted to understand their perspectives and expectations. Parents were very clear about wanting their children to be successful in school—something that had eluded most of the parents. The teachers were also clear that if the children came to kindergarten with good behavior and social skills,

then they were prepared to teach them the academic subject matter that focused on reading, mathematics, science, and social studies. The parents expressed some uncertainty and general lack of confidence in exactly how to help their children academically as well as a general uneasiness or fear about becoming directly involved in the schools. As mentioned earlier, the local public schools were not racially integrated until 1968 and many of the parents had attended racially segregated schools, had also dropped out before going to high school, and/or had struggled academically before dropping out. Thus, their unease with the current public school system was understandable.

The elementary school teachers were almost exclusively White as was the student population that closely resembled the highly educated population of the university town. The school system was generally regarded as academically excellent and

typically ranked number one or two in the state educational system based on standardized test scores. Many resources were available to help close the achievement gap between advantaged and disadvantaged children. In the kindergarten classes the Abecedarian children attended, the typical mother was a college graduate and the typical father had or was working on an advanced degree. In studying a representative randomly selected sample of classmates of the Abecedarian children each year, it was learned that the average kindergarten peer had an IQ of around 115 and that only one in eight children were from poor families. Almost all of the White children were from middle- and upper-income families. This fact undoubtedly contributed to social class consciousness and some stigmatization of the Abecedarian Project participants.

Random Assignment

Abecedarian Project experimental and control children were assigned randomly to the K–2 educational program, using a matched pairs design that rank-ordered children based on IQ scores taken when the children were 48 months old. Phase 2 provided a first-ever opportunity to experimentally compare the effects of early educational intervention for the first five years of life alone with those of receiving a high-quality K–2 educational intervention only, as well as receiving both the earlier and later educational enrichment programs. One of the four final groups received no additional systematic educational programs but did have the social and health services and the same generally high-quality public education received by the children in the other groups.

The Abecedarian school-age program was designed to strengthen the child's home and school educational environments, based largely on the view that the quality and availability of school resources and parent involvement in and support of children's academic work are important in their school success. For children whose parents had low educational attainment and often had negative school experiences, the program also sought to improve school–family connections and

mutual support. It was designed to be an approach that, if effective, could be adapted for use by other school systems.

An explicit objective of the school-age intervention program was to provide children with additional help related to teacher-selected academic materials. Specific activities focused mainly on reading and math concepts and skills because these are critical gateway skills to more complex material. The school-age intervention program was implemented by highly skilled and trained home-school resource teachers with master's or doctoral degrees. As advocates on behalf of children, they procured educational services or supports that could be of help to children, teachers, and families. Home-school resource teachers typically had a case load of 12 children per year.

Meetings With Classroom Teachers

Meetings with classroom teachers were held biweekly. A home-school teacher obtained information from the classroom teacher concerning the child's progress and curriculum information on which to base the home activities. The home-school teacher shared with the classroom teacher information about the most recent home contact, as well as suggestions about educational approaches. From these discussions specific activities were created for parents to implement with their children.

Meetings With Caregivers

Another major part of the home-school teacher's responsibility was to involve the child's primary caregivers, be they parents, grandparents, or older siblings, in the child's formal education. Approximately every 2 weeks a homeschool teacher met with the primary caregiver to accomplish three primary ends:

1. Provide information concerning the child's activities and progress in school.
2. Communicate the ideas and activities previously established in meetings with the classroom teacher, and provide specific home activities and guidance designed to attain these objectives.

3. Assist parents in understanding the rationale for the activities and in developing positive behavioral techniques for working with their children in response to school-related opportunities, issues, or problems.

The caregiver was asked to document the work on a special calendar. Once a month, the calendar was retrieved by the home-school teacher, in part, to document the program, and was exchanged for family gift certificates at local restaurants.

In summary, the Abecedarian home-school resource approach can be characterized as *targeted* on key academic skills that the child was being exposed to in his or her classroom, using a *guided mentoring program* for both classroom teachers and parents and *careful monitoring and review* of the child's progress by skilled, experienced, and emotionally engaging resource teachers. Home-school resource teachers met regularly as a group and were supported by curriculum and research staff.

Summer Camp

When the Abecedarian Home-School Resource Program was conceived, it was already well known nationally and locally that disadvantaged children tended to not keep up the expected pace of learning during the summer months between grades. To address this issue, the Abecedarian Summer Camp was created that made full use of city, county, and school resources to create a fun-filled, active, and developmentally oriented day program on weekdays throughout the summer. The summer camp made use of city parks and recreational facilities and activities and employed junior staff under the direction of the home-school resource teachers who infused academically relevant content in typical summer camp activities such as individual games, arts and crafts, swimming, sports, and cookouts. Table 3 summarizes the K–2 Abecedarian home-school resource teacher program.

As of 2014, all four of the original Abecedarian yearly cohorts have been followed at ages 8, 12, 15, 21, 30, and 35 years as depicted in Figure 1.

Outcomes and Findings

Outcome Measures

The strategy for estimating the impact of the Abecedarian early education approach concentrated on assessments of children in the treatment and control groups in key skill areas by individuals who were blinded to each child's treatment condition.

Birth to Age 5 Results

The results from the Abecedarian Project during the first five years present evidence of treatment benefits in language, cognition, and intellectual development. Figure 2, for example, shows the children's performance on standardized tests of development and cognition from 3 to 54 months of age. The treatment groups began to diverge significantly by the age of 18 months, such that from 18 months through 4 ½ years, the educationally treated children performed at significantly higher levels than did control children. A strong decline occurred over time in the control group children, consistent with the hypothesis of the toll of living in a low-resource and understimulating environment. In contrast, children in the educational intervention group continued to perform in the normal range. This difference between the two groups yielded a large mean effect size during the first five years of 1.05. Another way of comparing the groups is that on average, the children differed by more than 12 points in their IQ scores. Significant but somewhat smaller differences persisted into adulthood when they were last assessed on IQ at age 21.

Other cognitive/intellectual findings include the following:

The preschool educational intervention reduced the incidence of intellectual disabilities during the preschool years. Figure 3 plots the percentage of children in each group who earned normal range IQ scores (≥ 85) on standardized tests of intellectual development at ages 6, 18, 36, and 48 months. Of the educationally treated preschool children, 95% remained within normal limits at 48 months, whereas only 45% of control group children

Table 3 Summary of Abecedarian K–2 Educational Support Program

Individualized focus on academically related activities in school and at home
Emphasis on reading, mathematics, and writing
Master home/school resource teachers with 12 children and families per year
Development of an individualized and documented supplemental curriculum for each child
Explicit attention and action relevant to family circumstances, as needed
Summer camps with academically relevant experiences

Source: Adapted from Table 4, Summary of Abecedarian K-2 Educational Support Program, p. 8, Ramey, C. T., Campbell, F. A., Burchinal, M., Skinner, M. L., Gardner, D. M., & Ramey, S. L. (2000). Persistent effects of early childhood education on high-risk children and their mothers. *Applied Developmental Science*, 4, 2–14.

scored within normal limits. From a standardized test perspective, the preschool educational treatment group was about as ready for kindergarten as children from a middle-class population (95% ready), whereas less than half of the control group children scored as ready for kindergarten.

Some Abecedarian educational control group children benefited from other preschool programs in which they were enrolled. Margaret Burchinal, Marvin Lee, and Ramey (1989) reported observations that demonstrated the positive association between attendance at other preschool programs

Figure 2 Intellectual Scores for Early Childhood Education and Control Group Participants in the Abecedarian Project

Note: MCGCI = McCarthy General Cognitive Index; MDI = Mental Development Index; SB = Stanford-Binet.

and cognitive performance during the prekindergarten years for *control group children*. Benefits were proportional to exposure for members of the control group; however, that group's performance did not match that of the Abecedarian preschool educational group, perhaps because of later start dates and less intensive program exposure.

Abecedarian preschool educational intervention increased children's cognitive resilience to nonoptimal biological and behavioral conditions. The Abecedarian preschool educational treatment significantly ameliorated the effects of some biological and behavioral risk factors, including low Apgar scores obtained at birth, difficult early temperament as rated by parents, and mild fetal undernourishment as measured by anthropometry at birth. The primary mechanism for this increased resilience was responsiveness of their teachers and mothers.

Kindergarten to Grade 2 Results

Academic outcomes at the end of the primary grades represent a direct and practical test of the

four treatment groups. Achievement in reading and mathematics was considered the most important academic outcome because these two basic subjects are crucial to success in the later elementary grades and beyond. Moreover, they are the skills to which teachers, school administrators, the general public, and policy makers pay particular attention. Research on the effects on reading and math performance from the Abecedarian Project involved standard score results for reading and mathematics derived from the Woodcock-Johnson Psychoeducational Battery. These assessments were individually administered to children at school by independent assessors.

The resulting means for the age 8 standard scores conform to the hypothesized pattern for both reading and math, but more dramatically for reading than for math. Effect sizes for the three treatment conditions at age 8 were calculated relative to the mean and standard deviation for participants in the control condition. The effect sizes for reading achievement at age 8 vary from .28 to 1.04 for the treatment conditions. These effect sizes were consistent with the hypothesis about the onset and

Figure 3 Percentage of Abecedarian Sample in Normal IQ Range (>84) by Age 4

duration of the program; that is, the longer and more intense the program was, the larger the effect size would be. The most effective treatment condition was the preschool plus K–2 program, followed by the preschool only, and then the K–2 program only, relative to controls. Findings for mathematics achievement were similar to the findings for reading, although the effects were somewhat more modest (i.e., effect sizes ranging from .11 to .64). Overall, the K–2 supplemental educational program, by itself, was marginally significant for reading (with an effect size of .28) but not practically significant for mathematics (with an effect size of .11).

Follow-Up Studies After Educational Intervention Ceased

At ages 12, 15, and 21 years, all children were followed up and administered Woodcock–Johnson individual assessments of reading and mathematics. Figure 4 shows (in effect size metric) the performance of the three treatment conditions relative to the control condition at each assessment occasion.

With respect to reading achievement, the predicted stair-step pattern relative to amount of treatment is evident: Those in the birth to 8 years program had the highest reading achievement, followed by those in the birth to 5 years program, then those in the K–2 program only, with the controls scoring lowest.

A similar but less consistent pattern was obtained for mathematics with the main difference being the near equivalence of birth to 8 years and birth to 5 years programs at ages 12 and 15. Overall the impact of the preschool program was greater than that of the school-age intervention. That is, the K–2 program by itself had immediate positive impact on reading and math but, over time, the impact faded into nonsignificance both statistically and practically.

These academic achievement findings also are associated with some practical and cost-saving outcomes. For example, the preschool program, but not the K–2 program, is associated with significant reductions in retention in grade from 55% to 30% by age 15 and in placement in special

education from 48% to 24%. At age 30, children who experienced the Abecedarian preschool program were four times more likely than controls to have gone to and graduated from a 4-year college (23% vs. 6%).

Table 4 provides a brief synopsis of adult outcomes that are significantly associated with Abecedarian preschool attendance.

Replications and Extensions for the Abecedarian Approach to Early Childhood Education

The Abecedarian Project with birth to age 8 education was replicated in North Carolina and known as Project CARE (Carolina Approach to Responsive Education). The most intensive condition was compared to the same approach in a home-visiting format with comparable results for the more intensive treatment conditions but with no measurable positive effect for the preschool home visit plus K–2 program.

Beginning in 1984 the Infant Health and Development Program was created as an eight-site RCT of the Abecedarian approach for low-birth-weight and premature infants. A sample of 985 children from birth to age 3 years were enrolled in the program, which involved researchers at University of Arkansas for Medical Sciences, Albert Einstein College of Medicine, Harvard Medical School, University of Miami School of Medicine, University of Pennsylvania School of Medicine, University of Texas Health Sciences Center at Dallas, University of Washington School of Medicine, and Yale University School of Medicine. Abecedarian scientists at the University of North Carolina at Chapel Hill developed the protocol and supervised its implementation, and Stanford University collected and analyzed the outcome data at each of the eight sites. The program produced positive results in IQ, language, social development, and health at age 3 at each of the eight sites.

As of 2015, replications and extensions of the Abecedarian approach were in process in several countries, including Canada and Australia. Those trials were designed primarily to do two things:

Figure 4 Longitudinal Effect Sizes (in Standard Deviation Units) for Reading and Mathematics by Treatment Group

(1) explore degrees of risk in children from disadvantaged families, and (2) gain further knowledge about which children respond positively to the intervention and by how much.

Conclusion

It is clear that all children need substantial support to develop into healthy and productive

adults. Children who are conceived and born into families that have been poor and undereducated for generations face daunting challenges that block full participation in the activities and institutions that undergird productive and contributory life. Growing up poor and Black in a southern university town surrounded by affluent and educated White adults and peers poses its own set of challenges.

Table 4 Some Outcomes of the Abecedarian Preschool Educational Exposure Relative to Controls

<i>Significantly Increased</i>	<i>Significantly Decreased</i>
Kindergarten readiness	Intellectual disabilities
Reading achievement	Retention in grade
Math achievement	Special education
College attendance	Teen pregnancies
College graduation	Public assistance
Full-time employment	Smoking and drug use
Overall health	Depression
Maternal education	
Maternal employment	

The Abecedarian results indicate that high-quality early childhood education can be an important factor in helping children who start life with significant disadvantages to be more competent. Economists have used data from research on the Abecedarian Project to argue that similar programs more than pay for themselves in benefits to participants and taxpayers. To justify such programs on a cost/benefit analysis alone, however, is too narrow a focus. It is clear that classism and racism were not eliminated as negative factors that these children, and now, adults, must contend with. The Abecedarian approach represents a conservative estimate of the power of early childhood education to make life a fairer and more enjoyable existence from which children, parents, and society can reap real and socially meaningful benefits.

ACADEMICS AND ACADEMIC ASSESSMENT IN EARLY EDUCATION

This entry focuses on academic practices and assessment of academics in early childhood spanning preschool to third grade. *Academic content areas* as defined here include instructional content and teaching practices for the areas of literacy, mathematics, science, and social studies. The topics of academic instruction and associated assessment practices are vast and could be approached from any number of perspectives. The perspective taken here is to highlight core influences on academic content and practices in typical early childhood programs and elementary schools.

Three key topics are discussed with reference to multiple content areas: academic content standards, theoretically and empirically guided models of instruction, and academic assessments. The final topic area discusses the different types and purposes of assessments, inclusive of assessments for learning and assessments of learning. The focus here is on academic content and instruction in the United States within general education classrooms.

During early childhood, academic literacy content addresses building children's competence in fluently decoding words and in comprehending texts of increasing complexity and of both narrative and expository genres. Developmental precursors to decoding and comprehension include letter knowledge and phonological awareness, whereas concurrent content includes oral language, writing, and spelling. In mathematics, core academic content addresses mastery of conceptual understanding and procedural applications in number and operations, geometry, measurement and analysis, and patterning. In both these domains and increasingly in science, content standards are a primary driver of grade-specific instructional content.

Academic Content Standards

In the United States, there has been a notable increased focus on standards-based educational practices in recent decades. Standards-based

frameworks address both content coverage within academic areas and grade-specific expectations of what students should know after receiving a year of instruction. One goal of standards-based instruction is to have clear alignment between standards, curricula, and assessments. Inside state-supported prekindergarten and other preschool settings, standards have been associated with a move toward a more educationally focused environment and away from conceptualizing early childhood settings as custodial care with primary focus on nurturance and child care support for working parents.

Initially, the standards adopted in each state were unique and included widely varying scopes, sequences, and rigor of grade-specific expectations. In recent years there has been a movement, led by the states, to create common sets of educational standards and expectations for kindergarten through Grade 12. These standards address reading/language arts, mathematics, and more recently, science. These standards are represented in the Common Core State Standards and the Next Generation Science Standards. In social studies, although there is not a widespread adoption of common standards, the National Council for the Social Studies has put forward a framework for common standards. Most states, and the federally funded Head Start program, also have standards for state-funded prekindergarten programs serving 4-year-old students. These standards cover foundational skills for reading, mathematics, science, and social studies but also emphasize approaches to learning and physical and motor development.

A framework similar to the standards movement, but derived more from empirical research than from policy consensus, is the idea of *learning progressions*. Learning progressions have been proffered in science and math by researchers such as Douglas Clements. These academic content frameworks take into consideration what research in cognitive science and development indicates regarding the trajectories of understanding and abilities at different age levels to develop instructional sequences. In both academic areas, learning progressions have the goal of identifying a limited

amount of critical core content that educators should emphasize at each grade level, as a means of avoiding common problems of brief coverage of a wide array of concepts. A related goal is to avoid teaching students what they already have mastered, a problem implicated by many researchers investigating why some early learning gains may fade over time. Likewise, learning progressions attempt to map both quantitative and qualitative changes in students' conceptual understanding of mathematical and science content.

In early education settings there is limited instructional time that has to be allocated across the four core academic content areas and also, ideally, to art, music, physical education, and social development. Some critics of standards-based education are concerned about the prioritization of core academic areas over the other content areas. Even within core academic content areas there are differences in what is emphasized in classrooms. Specifically, research suggests, likely related to what assessments emphasize, that the time allocations to science and social studies have dropped substantially over the past decade, in favor of more time on reading and mathematics instruction.

Models of Instruction

Two controversies have dominated the discussion of what early childhood educators should teach. The first controversy concerns questions regarding whether academic or social-emotional content should be given priority; this controversy has been most prevalent among preschool and kindergarten educators. Significant research and theory support the relevance of children's social competence for their academic success. In particular there is clear evidence of the importance of children's self-regulatory control (of emotions, behaviors, and attention) within the classroom environment and of what has been called *approaches to learning*, which includes aspects of interest and engagement, persistence, and motivation to learn. These competencies are likely developmental precursors to more fully realized metacognitive and self-regulated learning behaviors observed in older

children, adolescents, and adults. The relevance of self-regulation and approaches to learning is not itself controversial. However, the relative emphasis on these and formal academic skills, and issues of their contention versus complementarity, have been a long-standing debate in early childhood.

Some researchers and educators have stressed the importance of a third aspect of development, related to more domain-general development. For example, Lilian Katz highlighted a distinction between academic and intellectual development goals, which are related to supporting children's dispositions toward learning. These dispositions include reasoning and problem-solving capacities that cut across specific academic areas but that may draw on academic skills and content knowledge. This perspective shares commonality with the focus on approaches to learning and with the focus on authentic learning contexts shared by many early childhood experts but also emphasizes attention to intellectual rigor and scientific relevance when selecting the content to which young children should be exposed. This latter point of emphasis stands in contrast to the sometimes trivial and non-intellectually stimulating activities observed in some early childhood classrooms.

The second, somewhat overlapping controversy concerns the nature of instruction for academic content; this controversy has been prevalent among educators across the early childhood grade span. Instructional models for early education have traditionally been described as those that derive from a constructivist, child-initiated learning framework and those models that endorse more educator-initiated, direct instructional approaches. Advocates of the former models have labeled these two approaches as *developmentally appropriate* and *developmentally inappropriate* practices, terms that have achieved widespread popularity but have been interpreted in quite diverse ways by educators and policy makers. A more pragmatic way of describing these instructional models is that they differ in how much and what kind of educator guidance is provided to children. One end of the continuum, particularly for preschool-age children, suggests very minimal educator guidance,

such that children are to be provided appropriate and relevant materials and encouraged to discover new skills and knowledge via their play alone and with peers. This version of constructivist practice is aligned with Jean Piaget's developmental stage theory of learning. The other end of the continuum suggests considerable educator guidance, such that children are provided models of and assisted practice with new skills. This end of the continuum is aligned with aspects of information processing and behavioral learning theories. A hallmark feature of evidence-based highly guided instruction is that it is *explicit* (e.g., the learning goal is clearly identified, the skill is modeled by educators, and students engage in supported practice with immediate corrective feedback).

With respect to K–3 reading instruction, dichotomized interpretations underpin decades of debate pitting those favoring whole language practices against those favoring instruction that includes explicit teaching of letters and phonics. Controversy is fueled by extreme depictions of each model, with whole language described as comprising only pure discovery learning and phonics-based models comprising only whole-group drills and passive worksheet exercises. Similar debates are ongoing regarding traditional versus more constructivist mathematics instruction. Critically, such characterizations often misrepresent the intentions of model proponents. That is, guided academic instruction can be highly interactive and motivating; likewise, student-initiated explorations can be academically beneficial and intellectually stimulating—thus, *both* instructional models echo the focus on intellectual rigor advanced by Katz.

Key components of these opposing instructional paradigms, particularly the constructivist approaches, derive more from philosophies of learning and teaching than from empirical investigation. However, especially for reading, there is now a substantial body of scientific evidence to inform educator practice. Importantly, accumulated evidence supports aspects of both constructivist and explicit instructional models. Using the pragmatic framework described earlier, this conceptualization of instruction includes gradations of teacher guidance, conditioned on the specific content to be learned

and the expertise level of learners. This differentiated-guidance model largely derives from social constructivist learning theories (i.e., guidance as *scaffolding*). Notably, the developmentally appropriate practice perspective has itself evolved toward encouraging teachers to intentionally mix minimally guided instruction and teacher-guided instruction and regularly engage in scaffolding.

For literacy, research indicates distinct cognitive processes associated with decoding and comprehending what one reads and correspondingly distinct instructional methods for each skill. Specifically, there is strong, convergent experimental evidence for teacher-directed, explicit instruction for code-related skills (i.e., phonological awareness, alphabets, phonics, and spelling) for children of all ability levels. In contrast, some more constructivist methods of teaching comprehension have been supported, primarily those including intentional instruction in comprehension strategies (e.g., visualization, questioning).

Comparably, in early mathematics instruction, experimental studies and meta-analytic reviews by researchers such as Russell Gersten suggest that explicit, systematic instruction, including computer-assisted instruction in arithmetic facts and operations, is effective in both general and supplemental educational settings. These findings are strongest for students who begin instruction with skills below grade level; initially advantaged students appear to progress well in mathematics in diverse instructional contexts. Notably, these evidence-based instructional practices are teacher guided but include active manipulations and verbalization of reasoning and problem-solving processes by students, practices derived in part from more discovery-oriented pedagogical models. Additionally, some preliminary research suggests the efficacy of hybrid models of early mathematics instruction where students initially explore problem types independently or with some conceptual instruction and subsequently receive relevant explicit procedural instruction.

Across content areas, accumulated empirical findings therefore suggest that high-quality, research-based academic instruction does not include only one pedagogical approach. High-quality instruction

can include differentiated amounts of guidance based on child or content characteristics. As an example, students with particularly weak decoding skills, such as those with a learning disability, may especially benefit from more explicitly guided instruction, whereas students with more advanced decoding and comprehension skills may particularly benefit from a loosely guided comprehension lesson focused on their construction of meaning from the text. Consistent with this perspective, studies on differentiated classroom reading instruction by researchers such as Carol Connor suggest that students may benefit from individualized profiles of code- and comprehension-focused instruction based on their initial skill levels. Similarly, some research suggests that the benefits of computation- versus schema-focused mathematical word problem small-group instruction may differ for students with varied initial skill levels.

Academic Assessments

Assessment of academic content takes numerous forms and has diverse purposes. One common way of classifying assessments is based on whether they serve the goal of assessment for learning (*formative*) or of assessment of learning (*summative*). Formative assessments are those used by teachers to inform instructional decision making, ideally in real time or with rapid turnaround. Many formative assessments are those developed by teachers and can include incidental questions posed to students during instruction and classroom discussions. Other formative assessments that are standardized, rather than teacher-developed, include *progress-monitoring measures*. These are also labeled as *curriculum-based measures* (CBMs) and include brief measures of specific academic skills.

The most common progress-monitoring assessments in early literacy are oral reading fluency measures that assess students' reading rate of grade-level passages, typically in 1-minute intervals. An example CBM for younger students is letter-sound fluency. In early mathematics, an example of progress-monitoring measure for first and second grades assesses fluency for solving mathematical computations (e.g., single-digit addition and subtraction problems). An

example of a measure for younger students is quantity discrimination fluency. CBMs are used to estimate rates of student improvement across brief time periods (as short as 1 week) and to document response to instructional interventions. In mathematics, CBMs typically differ from traditional mastery measures such that all forms include the full scope of content rather than discrete content keyed to each instructional unit. For both math and reading, a hallmark feature of progress-monitoring measures is use of forms of equivalent difficulty administered across time to gauge cumulative progress. Most of the widely used CBMs have established benchmark expectations for performance at different points in time for each grade level. A primary goal of these measures is to provide teachers with individualized yet psychometrically sound (i.e., reliable and valid) information regarding student learning so they can best differentiate instruction.

Related to this goal, formative assessment is a central feature in response to instruction (RTI) models, which are a form of multitiered levels of instruction reaching widespread implementation in elementary schools in recent years. RTI typically includes three tiers of instruction: Tier 1 is general classroom instruction; tier 2 includes small-group, more intensive instruction; and tier 3 is highly individualized, often one-on-one instruction. RTI is a system of differentiating instruction and identifying students with learning disabilities. In both cases, assessments play a prominent role. *Screening* assessments are designed to identify students who may be at risk for poor academic progress and who may qualify for tier 2 or tier 3 instruction. Screening measures "screen to" a criterion measure, typically a norm-referenced diagnostic assessment or a summative end-of-year assessment. Progress monitoring is utilized to track whether students are responding to their current level of instruction. Researchers such as Lynn Fuchs and Donald Compton are investigating issues such as the best specific measures to use for these identification purposes, where on continua to designate cut-points for routing students into more intensive instruction, and how to most validly use these formative assessments as part of a formal diagnostic process for special education.

Summative assessments of early academic content are more controversial, in that they typically are implemented as part of a high-stakes accountability system. *Summative* assessments are measures of content mastery implemented at the end of an instructional period (such as a school year) and are often aligned with the grade-level standards adopted by a state. These assessments are typically either *criterion-referenced* assessments, which compare student performance to established benchmarks for performance in their grade level, or *norm-referenced* assessments, which compare student performance to that of other students. Summative assessments of early academic content are more controversial than formative assessments, in that they often are implemented as part of a high-stakes accountability system.

One challenge in selecting assessment tools is to clearly specify the purposes for which they will be used, because a measure valid as a progress-monitoring tool may not have comparable validity as part of a diagnostic assessment for determining special education qualification. Likewise, it is important to distinguish between the validity of summative assessments as indices of student skill and the validity or appropriateness of the high-stakes purposes for which these measures are often used (a topic beyond the scope of this entry). Similarly, there can be a substantial gap between the goals of an accountability measure and of a teacher's informal classroom assessment. Teachers likely need access to a variety of valid measures, as well as their own content expertise, to accurately gauge student progress in learning.

ACCESSIBILITY

While research on early childhood programs and policies has led to an increased awareness of the potential benefits of quality early childhood education programs and their cost-effectiveness, access remains quite uneven. Accessibility to early childhood programs over time has developed into a complex system of funding streams, programs, and forms of delivery that vary greatly across the country. Access and access to quality are central issues very much present in relation to early childhood education. Children under the age of 5 may be enrolled in child care, Head Start, Early Head Start, preschool, or a home day care program. Programs are either federally funded, state funded, or locally funded. However, there is little to be said about the overall quality of programs, with the majority of services being low quality. This entry summarizes types of early childhood education programs, enrollment rates in these programs, inequities in accessibility for children in the United States, and access to quality programs.

Early Childhood Education Programs

The two main drivers of enrollments in early childhood education programs in the United States are the federally funded Early Head Start and Head Start programs and state preschool programs. Head Start is the largest program of the U.S. Department of Health and Human Services, and it provides comprehensive early childhood education, nutrition, health, and parental involvement services to low-income children and their families. It is also the longest standing program of its kind, as it has been in operation since the 1960s.

State preschool initiatives are much younger, with the majority of them having been started in the past two decades. These programs vary significantly in hours of operation, eligibility, funding, and standards of quality. Out of a total of 53 programs in 40 states, 29 are income targeted, and 14 are full day (with some states allowing variations within state programs). The state preschool

programs in Washington, D.C., Florida, Oklahoma, Vermont, and West Virginia rank among the highest in terms of access for 4-year-olds. The programs in Washington, D.C., Vermont, Illinois, New Jersey, and Arkansas similarly rank highest for access to 3-year-olds. Washington, D.C., New Jersey, and Connecticut provide the largest resources per child. On top of state programs, in the past few years there has been an increasing trend, albeit still small, for cities to either complement state preschool programs or create their own programs. This is the case for Boston, Denver, San Antonio, and Seattle, among others.

Child care programs, whether with federal support, state based, or locally based, while less likely to have educational content are also important providers of center-based services for children under the age of 5. These programs usually have different standards and regulations than preschool services and may be provided for extended hours. Some child care services are provided as a wrap-around to existing preschool programs.

Enrollments

For the purposes of this entry, early childhood education programs are defined as center-based programs with an educational focus. Head Start is one such type of program, as are state preschool programs. Currently, slightly over half of the children under age 5 are enrolled in some type of center-based program. Enrollment rates are higher for children in the preschool years, ages 3 to 5, but more predominantly so for 4-year-olds. These rates are slightly higher for White, African American, and Asian American children and somewhat lower for Hispanic children. Differences in enrollments by income or by parental education are also quite stark.

Enrollment rates have been strengthened in states that have state preschool programs. State preschool programs have been the main driver in the past couple of decades, even after having been strongly affected by the financial crisis that hit the United States in recent years. According to W. Steven Barnett and colleagues in *The State of Preschool 2014: State Preschool Yearbook*, total

state preschool enrollment now amounts to over 1.3 million children ages 3 and 4 in 40 states and Washington, D.C. With almost 800,000 children in Head Start and another 430,000 in special education programs, about 2.5 million children are currently being served by these types of early education services. Total enrollment is about 40% of 4-year-olds and 15% of 3-year-olds.

The rate of enrollment in these types of early education programs has grown slowly. Unlike the trends of other highly developed countries where universal public early childhood services are much more common, the United States has a much more limited system, far from providing universal access. It would take the United States more than 75 years at the current growth rate to enroll at least 50% of the country's 4-year-olds. Moreover, gains in access, and in particular, in access to high quality, have been uneven and quite dependent on state and local initiatives. Access is highly dependent on location. Currently, the Northeast has the highest access rates with 70% of its 4-year-olds enrolled in center-based programs. Similarly, enrollment rates in rural areas are about half of what they are in urban or suburban areas.

Access to Quality

Research has continuously highlighted the importance of quality in order to reduce achievement gaps and to gain long-term benefits on children's developmental trajectories. Quality, however, is not so much the rule but rather the exception. Many programs are too low in quality to generate lasting positive impacts on children. Generally, research has shown that the programs with the largest and longest lasting effects are more educationally intensive and expensive. The most effective programs have been part of public education and have had more highly educated, better paid teachers than Head Start and child care, reasonably small class sizes, and low child-teacher ratios.

In essence, among the various aspects highlighted for quality programming and structure are (a) a qualified staff, with bachelor's degrees in early childhood education or bachelor's degrees and state teaching certificates in early childhood education;

(b) teacher assistants with certification in child development or early childhood; (c) adequate compensation in line with the K-12 system; (d) low child-staff ratios (1 to 10 for preschool); (e) small group sizes (2 teachers to 20 children for preschool); (f) age-appropriate and research-based curricula; and (g) a system of monitoring and evaluation, supervision, coaching, and support by specialists.

In addition, there are important aspects of process and form that have been shown to be fundamental components of quality. Among these are providing ongoing opportunities to learn important skills, knowledge, and dispositions and emphasizing intentional teaching and individualized and small group instruction.

Early childhood programs vary tremendously in all aspects of quality, making access to quality services starkly defined by where a child lives. For example, Oklahoma has relatively high-quality programs, while also having high access rates. Some other states have created universal programs for 4-year-olds but dedicate too few resources per child, as is the case in Florida. Other states have quite large, high-quality programs but are mostly focused on economically disadvantaged children, as is the case in New Jersey.

Overall though, access to quality services is low. According to Milagros Nores and W. Steven Barnett, only about a third of 4-year-olds have access to programs of quality. On top of this, access to quality is also defined by race, income, education, and location. Children from low-income families are half as likely to be in a high-quality program as children from high-income families. Similarly, racial and ethnic minorities as well as rural children are less likely to have access to a high-quality program. This is also the case for dual language learners and children of immigrant families, according to the Center on Enhancing Early Learning Outcomes (CEELO).

Access for Infant and Toddlers

For children under the age of 3 years, access and access to quality services are quite scarce and in many regions nonexistent. Early Head Start is a key provider of services for children in this age

group, although the majority of children served are enrolled in child care. Less than 20% of infants and toddlers are enrolled in center-based programs, about 30% are in some type of relative or nonrelative care, and the majority of them, over 50%, are not enrolled in any type of services or consistent arrangement. What little is known about the quality of services for infants and toddlers has indicated that most programs are of low quality. Access to early childhood programs for infants and toddlers is less strongly defined by location (as it is low across the board) and somewhat more defined by income, parental education, race, and ethnicity, while at the same time remaining low for nearly every child in the country.

Determinants of Access

Although there is some evidence that different families have different preferences in terms of accessing early childhood education services, existing accessibility rates are highly policy driven. The states that have moved toward providing universal access (such as Florida and Georgia) have seen strong growth in participation rates in a very short period of time. The same has been true in New Jersey in the districts where universal preschool is provided (known as the Abbott districts). Consequently, policy and politics are the main drivers of enrollments. Strong recent initiatives for increased access and quality have come from the federal government, from the ballot, or from strong leadership at the state level.

ACCOMMODATIONS AND ADAPTATIONS

Accommodations and adaptations are supports incorporated into everyday environments that provide individuals with disabilities the same opportunities to participate and achieve as those without disabilities. For young children with disabilities,

this may include providing accommodations for inclusion in child care settings, removing barriers that impede access to participation in schools, and providing modifications that support individualized learning objectives. By supporting the participation and learning of young children with disabilities through accommodations and modifications, inclusive communities in which all children belong are created, thus also enriching the experiences of children without disabilities. This entry explores the concept of accommodations and adaptations in relation to young children with disabilities. Specifically, it distinguishes between accommodations and adaptations/modifications, addresses their legal basis, and explores various types of accommodations and modifications.

Definitions

Although accommodations and adaptations are often words seen in tandem, they are not the same. An *accommodation* is a change that is made to an environment, an assessment, or a learning experience that does not change the expected outcome for an individual with a disability in comparison to an individual without a disability. For example, even though a third-grade student with a learning disability is permitted the accommodation of more time to complete a math assignment, he is still completing the same assignment as his peers. Accommodations focus on *how* a student learns or negotiates an environment rather than on *what* a student is learning. Accommodations often allow students with disabilities access to an activity by removing barriers to participation and increasing the student's independence in completing a task or negotiating an environment. Accommodations modify the environment, the manner of presentation, or the child's method of responding without lowering the standard for the student with a disability.

An *adaptation* or a *modification*, as it is referred to legally, is a change made to an environment, assessment, or learning experience that lowers the expected outcome for the individual with a disability in comparison to others. For example, giving a student with Down syndrome fewer and easier math problems on an assignment alters the magnitude and

level of the learning experience; what the student is learning is different from that of the other students in the class. Adaptations/modifications, in contrast to accommodations, modify the learning objectives, instructional content, and/or method or criteria of evaluation to meet an individual's different needs and abilities in ways that alter what the child is learning or the standard to which the student is evaluated. Like accommodations, a modification may also lead a child to greater independence, albeit at a level below that of his peers without disabilities.

For young children with disabilities, accommodations and modifications are key components to promoting success in all types of settings, including those found in homes, child care centers, and school classrooms. Adjusting developmental and learning opportunities in these settings through the use of these supports provides young children with disabilities enriched, individualized learning experiences, including better access to the general education curriculum in school programs. It is essential that accommodations and modifications are not one-size-fits-all. One must not only consider the specifics about the child when identifying accommodations and adaptations, such as age, placement, specific strengths, and identified goals, but also the level of evidence for the practice that exists in the research literature.

Legal Basis

A number of different laws require the use of accommodations and modifications as a primary means for guaranteeing that individuals with disabilities will have equal opportunity to participate in the mainstream of our society and, in particular, in our schools. Most broadly, the Americans with Disabilities Act (ADA) prohibits discrimination on the basis of disability. This includes making "reasonable accommodations" to policies and practices in child care settings so that children with disabilities can be included and benefit from the services provided.

The Individuals with Disabilities Education Act (IDEA) protects the rights of children with disabilities to receive a free appropriate public education.

It is an education law that provides financial assistance to states for special education programs and services and covers children starting from birth. All preschool and school-age children receiving special education services receive an individualized education program (IEP), a written document that delineates the measurable annual goals for a student's educational program and the supports and services that will be provided so that the student can achieve those goals. For school-age children, the child's goals and identified supports are referenced in terms of the general education curriculum. Accommodations and adaptations may appear within various sections of the IEP and encompass participation in regular education classes as well as extracurricular and nonacademic activities. The 2004 reauthorization of IDEA added a section to the IEP specifically focused on state and district-wide accommodations for assessment.

For preschool children, covered under Section 619 of Part B of IDEA, the focus is more on developmental skills and age-appropriate pre-academics, which may be referenced to state learning outcomes for this age group if available in a state. For infants and toddlers with disabilities covered under Part C of IDEA, the use of the words "accommodations and modifications" is not usually applied, although the same basic principles are pertinent. A main difference is that the proposed outcomes are developmental rather than academic and such interventions generally occur in natural environments in the home and other community settings (e.g., child care, playgrounds, grocery stores) rather than in schools or preschools.

Similar to the ADA, Section 504 of the Rehabilitation Act also focuses on civil rights, specifically public and private programs and services that receive federal assistance. Some children who do not qualify for special education under IDEA may qualify under Section 504, which focuses on removing barriers and providing children access to education. Children covered under Section 504 may include children with asthma, cancer, allergies, epilepsy, diabetes, or certain mental disorders—basically those that do not require specially designed instruction but who may need accommodations to support access to learning and learning

environments, because they have been diagnosed with a physical or mental impairment that substantially limits a major life activity. Although not mandated by law, many school districts develop Section 504 plans, which identify the accommodations and modifications that will be made to support a student. States do not receive funds to support the implementation of Section 504 nor is there the same degree of federal oversight as IDEA. Students who qualify for special education under IDEA generally do not also have Section 504 plans; Section 504 protections are generally covered by the IEP.

Types of Accommodations and Adaptations

Accommodations and adaptations are generally broken down into various types. Although there is some variation, they usually are categorized in terms of changes in presentation, response, setting, and timing/scheduling. Although this schema was developed primarily for school-age children in academic settings, the examples here also include children younger than kindergarten age in non-school settings; many examples are general enough to be independent of age and/or setting.

Changes in *presentation* refer to creating additional or alternative visual, auditory, and/or tactile inputs for accessing the pertinent learning materials or aspects of the environment that are integral to a task. For example, although most preschoolers learn to wash their hands by responding to teacher verbal instructions, some children with disabilities, such as those with autism, intellectual disabilities, or other conditions in which auditory input might not be optimal, would benefit from a set of pictures near the sink that depict the steps in hand-washing. This visual accommodation permits the child to learn the same behaviors as other students but with additional support. Other presentation changes might include providing directions in different modes such as verbally and in print; a list of important vocabulary words; manipulatives to complete math problems; shorter or simpler assignments; alternative activities or assignments; and visual or graphic organizers. Changes in presentation may also include the use of specialized equipment and

modifications of materials, such as highlighting pertinent words in printed material; using Braille, large print, text-to-speech technology, or audiobooks; providing a calculator or abacus; and using adaptive cups, spoons, toys, writing tools, and seating/standing arrangements.

Changes in a child's *response* refer to the manner in which a child demonstrates knowledge once the task has been presented or to the level at which a child responds. For example, a third-grade child with cerebral palsy who is unable to control her arm movements but who has minimal speech involvement could electronically record her stories or use a voice recognition system for speech-to-text conversion rather than writing them on paper. Other response changes might include use of Braille, sign language, computer, or a dedicated communication device; use of a scribe to record student responses or take notes; alternative assignments and activities, including shorter and easier tasks; and pointing with a finger rather than speech to make a selection.

Changes in *setting* refer to providing alternative locations or conditions for a task, taking into consideration seating, placement next to other students, noise level, and comfort. For example, a mother who tries to engage her toddler with autism in his bedroom laden with toys finds that the child rapidly moves from toy to toy without more than a few seconds engagement with any, especially when she tries to direct his attention to specific items. Upon advice from her early intervention provider, she modifies the setting by moving playtime to a corner in the basement, devoid of all but five of the child's favorite toys. Rather than trying to redirect his attention, she follows the child's lead by imitating his actions on a similar or identical toy. This change in setting, along with a modification in presentation, results in the child now engaging each toy for several minutes. Other accommodations and modifications to a *setting* might include providing headsets to block noise; removing distractions from the learning setting; adjusting student seating to be closer to the teacher, screen, or board or away from the door or windows; considering one-to-one, student pairs, or

small group learning arrangements; adjusting lighting; using an FM system for children with hearing impairments or auditory processing challenges; using tape or magnetic strips to secure paper or other items to a surface; and using individualized dishpans for sand or water play.

Changes in *timing and scheduling* refer to allowing more time to complete a task or modifying how time is organized in the completion of a task. For example, many children with disabilities may tire easily because of the nature of their disability. Allowing a child the opportunity to take more frequent breaks may permit him or her to complete a task with greater success and perhaps avoid meltdowns that could disrupt the classroom. Other timing and scheduling accommodations and modifications include breaking an activity into smaller, less time-consuming tasks; giving a child a desk version of the schedule; signaling transitions between activities ahead of time; and modifying the schedule to complete more difficult tasks when the child is most attentive.

ACCOMMODATIONS FOR ASSESSMENT

All children, including those with disabilities, are required to take part in district and statewide assessments. States generally begin testing in third grade. Providing accommodations and adaptations/modifications for children with disabilities ensures that such assessments more accurately measure a child's achievements. This entry reviews district and statewide assessment accommodations for children with disabilities, specifically the legal basis of these accommodations, the identification of accommodations, the use of alternate assessments, and assessment accommodations for English language learners (ELLs) with disabilities.

Legal Basis

The No Child Left Behind Act (NCLB) of 2001 required states to develop standardized assessments to measure the basic skills of students as a means of evaluating the extent to which schools in a state were meeting academic standards. The purpose of the legislation was to improve the quality of the schools and to ensure that all children have an equal opportunity to receive a quality education. NCLB mandated that no less than 95% of student scores be included in the report of adequate yearly progress (AYP). Effectively, this requires schools to report the scores of all students, prohibiting the elimination of the lowest scores. In reporting the scores, schools must disaggregate the results by subgroup, including those with disabilities.

The reauthorization of the Individuals with Disabilities Education Act (IDEA) in 1997 greatly

strengthened the role of regular education in programs for students with disabilities by requiring that children's goals relate to the regular education curriculum in student individualized education programs (IEPs). IDEA reauthorization in 2004 further formalized participation in the general education curriculum by requiring that a student's IEP include a written statement of accommodations and modifications for state and district standardized testing. Furthermore, all states were mandated to develop written policies for acceptable assessment accommodations. Children with disabilities who are not covered under IDEA, but who receive accommodations under Section 504 of the Rehabilitation Act, must also be included in state assessments with the use of accommodations as appropriate.

The Identification of Accommodations

An IEP team must decide whether or not a child with a disability will participate in the general state assessments. For many children with disabilities, it is a matter of making accommodations to the test setting, manner of test presentation, nature of the child's response, and/or the timing or scheduling of the test so that the child's achievements can be measured accurately. When such accommodations are made, they do not change the level of content or the criteria for evaluation when compared to those used for children without disabilities. For example, a child might be given more overall time and tested in a separate room with 5-minute breaks scheduled every half hour. Someone else might read the test questions and then write down the child's verbal responses. However, the content being tested is the same as for students without disabilities.

Tests might also be given in smaller groups, in rooms with fewer distractions, sitting near the teacher or aide, or using special lighting or acoustics. Other presentation-based accommodations might include large print or Braille editions of tests, sign language interpreters or amplification, simplified directions or underlined key words, repetition of test directions, and cues on answer forms to reduce

misplacement of answers. The manner in which a child records his responses could include recording answers orally on a tape recorder or using speech-to-text conversion software; signing responses; using assistive communication devices, word processors, or computers; and adapting answer forms to accommodate larger handwriting or limited range of motion. Time and scheduling accommodations might include multiple shorter test sessions, use of frequent rest breaks, and not having a time limit.

All accommodations for assessment are described in detail in the child's IEP and are to be selected from the state's approved list of accommodations. Accommodations selected for assessment do not have to be the same as those selected for instruction. In fact, it is recommended that both be considered separately as the needs of the student in each situation may differ.

Alternate Assessments

For a small number of children with the most severe disabilities, the general state assessments will not be appropriate even if accommodations are made. For these children, an *adapted* or *modified* assessment, called an alternate assessment, is given that lowers the expected standards for the individual in comparison to others without disabilities. In this case, the IEP must include an explanation of why the child will not be assessed using the general state assessments and a description of how the student will be assessed. There are three alternate assessment options:

1. Alternate assessment based on grade-level academic achievement standards for students who may require alternate contexts and supports that cannot be accommodated on the general tests; currently, only a few states offer this option.
2. Alternate assessment based on modified academic achievement standards for students who are learning grade-level content but whose expectations for achievement are below grade-level proficiency.
3. Alternate assessment based on alternate academic achievement standards for students

with significant cognitive disabilities. This option assesses content at less breadth, depth, and complexity with a standard of proficiency that is lower than the general assessment.

English Language Learners With Disabilities

The achievements of English language learners (ELLs) can be misrepresented by standardized assessments. To address their unique needs, testing accommodations for children with disabilities who are also ELLs must include both disability-related and linguistic accommodations. State accommodation documents typically address acceptable accommodations for ELLs with disabilities.

ACCOUNTABILITY IN EARLY CARE AND EDUCATION

This entry provides an overview of accountability in the current context of early care and education (ECE). It begins by defining accountability and explains why accountability is important. Next, the entry specifies who in ECE is accountable, what ECE providers are being held accountable for, how accountability is measured, and what recent policy developments are affecting ECE accountability. The entry concludes with a review of the implications of accountability for policy makers, administrators, teachers, parents, children, and the public at large.

Accountability Defined

The term *accountability* in the area of public policy is commonly defined as answerability, liability, and the expectation of account-giving. Accountability for ECE includes informal accountability as well as formal methods such as monitoring, program evaluation, the use of data for continuous quality improvement, and collection of child assessment data to assess learning outcomes.

Early Care and Education Defined

In this entry, the term *ECE* refers to child care (both family child care and center-based care), Head Start, prekindergarten (pre-K), and kindergarten. Table 1 presents the major programs, purposes, and associated accountability details at a glance. Historically, federal, state, and local governments have partially offset the costs of ECE (with parents paying for the majority of child care and private pre-K services) and in recent years, investments in this area have increased.

Why Is Accountability Important?

Accountability systems that are well designed and implemented can provide data that are useful to tailor quality improvement activities to address

needs, hold ECE service providers to higher quality standards, provide evidence on the benefits of particular ECE services or programs, and ensure that public dollars are spent on intended purposes.

Accountability systems are often comprised of the following elements: standards, data processing procedures, and reporting mechanisms. Accountability systems can focus on inputs (such as funding), outputs (such as the numbers and types of children who are being served), processes (such as the quality of care at the classroom level), and outcomes (such as children's school readiness or parental employment). Moreover, accountability can focus on programs as a whole, specific geographic areas, or particular populations. Effective ECE accountability systems articulate what aspect of ECE is being held accountable, who is being held accountable, and how accountability instruments and systems work.

Accountable to Whom?

ECE services and programs are accountable to a range of stakeholders. Parents are the primary audience for ECE accountability as they are responsible for choosing and paying for most of the ECE costs. Parents hold ECE providers accountable by deciding whether to continue to use a particular ECE provider based on their satisfaction with the quality of care. As public funding for ECE has increased, the audience of ECE accountability has also expanded to include policy makers, program administrators, and the public at large.

Specific target audiences of ECE accountability systems vary by program. For example, kindergarten teachers are accountable to principals who report to local school boards and ultimately state education agencies. State-funded pre-K providers are accountable to school districts and states, whereas Head Start providers are accountable to the U.S. Department of Health and Human Services, and child care providers are accountable to the state agency overseeing services. In contrast, privately funded pre-K providers and child care providers have only been accountable to parents. However, with increased public funding for pre-K

and child care, these providers are also being held accountable to the state or local agencies that administer the public funds.

Accountable for What?

Accountability requirements vary across ECE programs. Most publicly funded ECE programs' accountability requirements cover, at a minimum, fiscal issues, program management systems, and standards related to health and safety. All ECE providers are held accountable for offering services to children and families, effectively administering those services, and properly managing funds.

Health and safety standards vary by state and program but most child care standards cover prevention and control of infectious diseases, building and physical space safety, and training of providers regarding health and safety practices.

Separate program-level, classroom-level, teacher/caregiver-level, and child-level accountability requirements exist for each publicly funded ECE program, but these vary substantially. Across ECE programs, accountability standards exist regarding the hours and days of services that must be offered, the types of services that are available, and methods for recruiting children, but the specific standards vary by program. Similarly, ECE program standards exist regarding classroom practices, such as requirements for specific curriculum or standards related to teaching practices. At the teacher level, some ECE programs have specific standards related to teacher qualifications and professional development, and others include standards related to interactions between teachers and children.

With increasing public funding, some ECE programs are required to assess children's learning outcomes. Moreover, many programs require an independent evaluation that documents the quality of instruction and the student learning outcomes.

How Are Programs and Providers Held Accountable?

A range of accountability systems currently exist that employ different methods of data collection, analysis, and reporting. Historically, accountability

for ECE was informal; instead of relying on data, parents used judgments, observations, and portfolios that included pictures of children and samples of materials to determine whether they would continue to use an ECE provider. Parents can also make decisions about their child's participation with specific providers based on whether they are accredited by national accrediting bodies such as the National Association for the Education of Young Children or the National Association of Family Child Care.

Publicly funded ECE programs are held accountable with more formal data collection, analysis, and reporting mechanisms. The accountability systems vary by program, but many ECE programs use similar instruments to evaluate teacher interactions, classroom quality, and child outcomes. The instruments that are most common to assess teacher interactions and classroom quality are the Classroom Assessment Scoring System, which rates the quality of interactions between teachers and children, and the Environment Rating Scales, which evaluate the overall quality of child care centers and family child care homes. The most common instruments to assess child outcomes include Teaching Strategies GOLD, the Work Sampling System, and the Child Observation Record.

While the instruments to evaluate classroom quality and child outcomes are similar across programs, the accountability systems differ. For the most part, child care providers are held accountable for meeting licensing standards through regular submission of paperwork that demonstrates standards are met along with periodic monitoring visits. Trained licensing specialists conduct site visits to ensure compliance with health and safety standards, review files, and verify that submitted paperwork is valid.

Head Start and Early Head Start programs are held accountable through a number of systems and mechanisms including, but not limited to, regular self-reporting that the program meets performance standards, ongoing assessments of classroom quality using a valid and reliable observation tool, regular onsite monitoring visits from an independent team overseen and required by the federal program, and child assessment data collection and reporting.

Table I Major Publicly Funded Early Care and Education Program Accountability at a Glance

<i>Program</i>	<i>Who is accountable for the program?</i>	<i>What is the program accountable for?</i>	<i>How are programs held accountable?</i>
Child Care	U.S. Department of Health and Human Services (HHS) oversees the Child Care and Development Block Grant (CCDBG) and each state and territory's Child Care and Development Fund administrator is responsible for oversight. Some states have a decentralized administrative structure and counties have administrative oversight of CCDBG.	• Fiscal management • Health and safety: prevention and control of infectious diseases, building and physical space safety and health, safety training appropriate to the program setting • Supporting enhanced quality	Licensing/monitoring that requires self-report, paperwork review, and onsite observation and review. Some states publicly report ratings. Quality and rating improvement systems (QRISs) require more intensive paperwork, onsite review, and public reporting.
Head Start/ Early Head Start	HHS provides federal oversight of Early Head Start and Head Start, and each local grantee is accountable for proper administration of the programs. Grantees include large and small community-based organizations as well as school districts.	• Fiscal oversight and program management • Governance, including human resources management, facilities, and equipment • Recruitment, selection, enrollment, and attendance • Health, nutrition, and mental health • Family and community partnerships • Services for children with disabilities • Transportation • Education and development	Regular self-reporting that the program meets performance standards, ongoing assessments of classroom quality using a valid and reliable observation tool, regular onsite monitoring visits from an independent team, and child assessment data collection and reporting.
Prekindergarten	In most states, the state education agency is responsible for oversight of state-funded pre-K and in turn school districts, schools, and, in some states, community-based organizations are accountable for provision of ECE services. The U.S. Department of Education is responsible for a small portion of overall pre-K funds through grants to states.	Varies by state but may cover: • Teacher degrees and credentials, teacher professional development • Screenings/referrals and support services • Curriculum and classroom interactions/quality • Class size • Increasingly focused on child outcomes	Varies by state but most require at least annual documentation and follow-up on-site visit to verify that requirements are met, accompanied by visits from trained monitors. Some states require that an independent evaluator collect program-level, classroom-level, and child-level data to answer questions about the quality and impact of program.

(Continued)

Table I (Continued)

<i>Program</i>	<i>Who is accountable for the program?</i>	<i>What is the program accountable for?</i>	<i>How are programs held accountable?</i>
Kindergarten	Provides half- or full-day education to 5-year-olds. Principals and school boards are required to ensure that kindergarten classrooms follow all state and local requirements (as well as federal requirements for those classrooms that offer services that are provided using federal funds).	Varies by state and district but many are aligned with early learning guidelines and are designed to support: • Children with developmentally appropriate early educational experiences • Social-emotional, cognitive, and physical development • Increasingly focused on academic outcomes in the domains of mathematics and English language arts	Kindergarten classrooms typically follow same accountability standards as elementary schools. Typically principals are responsible for assessing and monitoring the quality of teaching and teachers are responsible for assessing student learning.

Most pre-K programs are held accountable through ongoing monitoring systems that require documentation verifying that requirements are met, accompanied by visits from trained monitors. Some states require an evaluation of the pre-K program in which an independent evaluator collects program-level, classroom-level, and child-level data to answer questions about the quality and impact of the program.

Kindergarten programs are held accountable through the same systems as elementary schools. Typically, principals are responsible for assessing and monitoring quality at the classroom level through observations and teachers are accountable for student outcomes. Kindergarten teachers are increasingly being held accountable for growth in student achievement as states are changing their teacher evaluation requirements.

Recent Policy Developments Influencing Early Care and Education Accountability

In recent years, a number of new policy developments have supported more formal accountability of ECE. These include the development of early learning standards, the development and implementation of quality rating and improvement systems,

the development and use of kindergarten entry assessments, and new federal ECE initiatives, including the Race to the Top—Early Learning Challenge (RTT-ELC) grant, the Preschool Development and Expansion grants, and the Early Head Start/Child Care Partnerships grants.

Early Learning Guidelines

Each state has created early learning standards or guidelines that define the desired content and outcomes of young children's education. Most state standards include domains that cover cognitive content areas (such as early literacy and mathematics) as well as physical growth and development, social-emotional development, and learning styles. The purpose of the standards is to guide teaching, provide parents with information about what they can expect in terms of their child's development, and align curriculum from early childhood through kindergarten. Some states are aligning child outcome measures to the early learning standards to create more cohesive systems of accountability.

Quality Rating and Improvement Systems

A quality rating and improvement system (QRIS) is a systemic approach to assessing, improving, and communicating the level of quality of ECE. It is

typically administered by state agencies. Most QRISs offer parents information about the quality of each participating ECE provider. QRIS accountability standards vary by state, but most states provide ratings in the following categories: (a) physical space and building quality, (b) administrator and teacher qualifications, (c) program administration, and (d) family partnership and engagement. Other indicators of quality used in QRISs include curriculum, interactions between children and caregivers, and accommodations for children with disabilities.

In recent years, some states have begun to include data on teacher quality and child outcomes as part of their QRIS. The goals and accountability mechanisms in QRISs differ. For example, some QRISs are designed with the goal of raising child care quality above the basic requirements of child care licensing, some are designed to provide parents with information, and others are designed to enhance early learning outcomes. Regardless of these differences, most QRISs report ratings to providers, parents, and the public at large to hold programs accountable for quality and guide quality improvement activities.

Most QRIS systems require ECE providers to submit paperwork that demonstrates the provider meets the quality standards, engages in a self-assessment process that reflects the indicators of quality, allows an outside independent observer to use a valid and reliable observation protocol to assess quality, and engages in a continuous improvement process. Some systems require that the providers assess children as part of the QRIS or require independent assessors to collect child outcome data to verify that QRIS levels are associated with increased child outcomes.

Kindergarten Entry Assessments

Kindergarten entry assessments (KEAs) are now being used by a majority of states to provide a snapshot of children's development. KEAs can be used to screen children to identify developmental concerns, to provide teachers and parents with information that can be used to support children's development, and to provide policy makers with information

about trends over time or differences among groups to inform policy and funding decisions.

Federal Initiatives

The RTT-ELC, Preschool Development and Expansion grants, and the Early Head Start/Child Care Partnerships grant program each include specific accountability provisions regarding administration (such as accountability standards for eligibility), provision of services, and child outcomes. The RTT-ELC grants support QRIS and kindergarten entry assessments and the Preschool Development and Expansion grants also support the use of kindergarten entry assessments. The Early Head Start/Child Care Partnerships grant program is designed to support partnerships between Early Head Start and child care, and participating grantees are required to follow separate program, classroom, teacher, and child accountability standards.

Considerations

Each state is responsible for child care licensing and monitoring standards as well as for all aspects of pre-K education with substantial variation in accountability standards and systems across states. Accountability standards and systems regarding who must obtain a child care license, what training is required, how many children can be cared for, and what the physical space requirements are vary by state.

Adding to the complexity, each major ECE program currently has different accountability requirements and systems and requires ECE providers to collect and report accountability data and, in some instances, to be open to monitoring site visits and observations. Each publicly funded program has articulated accountability standards that hold the programs accountable to taxpayers. Publicly funded programs are subjected to the government auditing standards, designed to ensure transparency in allocation of public dollars and to ensure public funds are spent for the intended purpose. With public support, the specific accountability standards for child care, Head Start, pre-K, and kindergarten have to reflect the different intended purposes of these programs.

ECE providers are increasingly collaborating or blending funds from child care, Head Start, pre-K, and other federal or state programs. The differences in accountability requirements can present challenges for providers attempting to create more seamless services for families. Moreover, without aligned accountability measures, ECE providers can be faced with multiple conflicting accountability requirements that take time away from providing high-quality services. For example, a large community-based organization that provides child care, Head Start, and pre-K could be required to accommodate more than five independent observers—one from the national accrediting body, one from child care licensing, one from QRIS, one from Head Start, and one from the state education agency. Similarly, teachers could be required to administer multiple different child assessments to meet the accountability requirements of each separate program.

ECE accountability requirements should be developed with an understanding that the purposes of accountability systems differ for parents, teachers, policy makers, and the public at large. Accountability requirements that are developed in the absence of consideration of how the accountability data will be used by different stakeholder groups can create a burden without actually providing information that improves ECE services.

Without clear articulation of how accountability data will be used, the “accountability system” can result in a number of negative consequences. ECE providers can spend too much time collecting data rather than providing quality instruction, data collection can be duplicative when dealing with competing accountability requirements, and data might be misused or misinterpreted, leading to inappropriate instruction.

Well-designed accountability systems protect the well-being of children and support their development, take into account the needs of parents as well as external stakeholders, and consider the way the system can be used by ECE program administrators and educators to provide high-quality ECE to young children. To be most effective in holding programs accountable for positive outcomes, it is important that stakeholders consider all aspects of

accountability system design and use. When accountability systems work as intended, stakeholders are satisfied and children and families get the high-quality care and education they deserve.

ACCREDITATION

In the early childhood profession, accreditation systems assess the quality of early care and education programs that serve young children in group settings, as well as university/college educator preparation programs that prepare early childhood professionals, including teachers. Accreditation provides a systematic approach for a profession to agree upon and identify program quality. In addition, the process of attaining accreditation is a method for programs to improve and sustain quality. Programs achieve accreditation status when self-evaluation is complete and evidence is provided to an accrediting body that standards-based criteria have been met by the program. As an objective standard of quality, accreditation provides consumers with valid information that can be helpful to parents seeking care and education for a young child or an individual who is seeking an educator preparation program, as well as funders seeking sound investments. This entry first gives an overview of accreditation systems and discusses the standards and criteria for accreditation. It then discusses why accreditation standards can be controversial, how accreditation is received, and how accreditation relates to state regulation and quality rating systems.

The status of accreditation recognizes that a program or organization has met designated standards as determined by an accrediting organization. Accreditation systems focused on programs

that care for and educate young children may accredit child care centers, school-age programs, family child care programs, PreK–12 schools, recreational camps, residential programs, or family service organizations with a focus on family and children. Educator preparation programs that lead to an undergraduate or graduate degree at 4-year higher education institutions may be accredited by the Council for the Accreditation of Education Programs (CAEP), and early childhood associate degree programs may be accredited by the NAEYC Early Childhood Associate Degree Accreditation (ECADA). For example, a university early childhood bachelor degree program may be accredited by CAEP, a community college early childhood associate degree program may be accredited by ECADA, and a child care program may be accredited by the National Association for the Education of Young Children (NAEYC). Individuals are not accredited; rather, they may earn a credential or a degree, such as a child development associate credential (CDA), national administrator credential (NAC), associate's degree, or a bachelor's degree.

Accrediting bodies are typically not-for-profit organizations with strong links to the profession, such as the National Early Childhood Program Accreditation (NECPA), or religious organizations, such as the National Lutheran School Accreditation (NLSA). Many accreditation systems are national, although there are some regional accreditation systems, such as Florida's Accredited Professional Preschool Learning Environment (APPLE). These organizations seek to advance their mission by creating standards and an accreditation process that encourage quality improvement of programs. For instance, if part of an accrediting body's mission is to advance high-quality learning environments for young children, the accreditation system would include criteria about indoor and outdoor environments. An accrediting body with a mission to advance educator preparation programs that produce effective teachers would have standards and criteria about pedagogy.

Since the mid-1980s accreditation of early care and education programs has played an important role in professionalizing the field of early childhood

education. In 1985, NAEYC began accrediting programs serving children from birth to kindergarten age and before and after school-age programs. Other early care and education program accrediting systems, including the NECPA system, began in the early 1990s.

Accreditation of educator preparation programs began in 1954 with the National Council for the Accreditation of Teacher Education (NCATE). Over its history NCATE moved to an outcomes-based assessment system. For example, rather than assessing only what objectives are listed on syllabi, criteria are also assessed regarding the outcomes of state or national exams taken by teacher candidates. In 2013 NCATE and the Teacher Education Accreditation Council (TEAC) combined to form the Council for the Accreditation of Educator Preparation (CAEP). In 2006, NAEYC's ECADA began accrediting early childhood associate degree programs.

While the primary focus of accreditation systems is to assist programs in providing care and quality learning experiences for young children, a parallel focus is on assisting families in selecting quality programs for children. In addition, accreditation status assists funders in identifying programs that have objectively demonstrated achievement of specific outcomes. To assist in disseminating information to consumers and funders, most accreditation systems have websites with an accredited program search function to locate accredited programs.

Accrediting systems develop procedures that programs must complete as they work to achieve accreditation. Accreditation systems typically require programs seeking accreditation to meet eligibility criteria, engage in self-study, provide evidence that criteria are met, and allow the accrediting body to verify the extent that criteria are met. The accrediting body then reviews the program's documentation and decides whether or not to award accreditation for a designated period of time. Programs that achieve accreditation then agree to engage in continuous quality improvement based on feedback. Before accreditation status is about to expire, programs then may engage in a renewal process to maintain accreditation.

Standards and Criteria

A program or organization seeks to achieve accreditation status in order to increase quality and receive recognition for meeting quality standards. Standards are developed by the accrediting body that allow for variability in how a program meets standards. For instance, an educator preparation program may have a standard that teacher candidates differentiate instruction to meet the needs of learners. Programs may prepare students to achieve knowledge and skills in differentiated instruction, while utilizing a variety of instructional methods.

Based on the organization's standards and by seeking advice of experts in the field who are knowledgeable of current research and best practices, the accrediting body develops criteria that must be met by the program seeking accreditation. In order for criteria to be valid, it must be aligned with standards, researched-based, and focused on outcomes. For example, there are 10 NAEYC Early Childhood Program Standards: dealing with relationships, curriculum, teaching, assessment of child progress, health, teacher preparation and qualifications, families, community relationships, physical environment, and leadership and management. Each standard has several topic areas with specific criteria, for instance, Standard 2: Curriculum has a topic area focused on technology and a criterion about the use of developmentally appropriate media in early childhood curriculum.

Standards reflect the mission and focus of the accreditation system. In contrast to NAEYC's Early Childhood Program accreditation system, educator preparation programs have standards focused on teacher candidate competencies. ECADA accredits early childhood associate degree programs and has seven standards focused on child development and learning, family and community, assessment, teaching approaches, content knowledge, professionalism, and field experiences. CAEP accredits bachelor's and master's degree programs and has five standards that include sets of standards dealing with content and pedagogical knowledge, clinical partnerships and practice, candidate quality, program impact, and quality assurance. For ECADA and CAEP, each standard has key elements and measurable criteria.

Accrediting bodies may have varying criteria based on the mission and vision of the overseeing organization. For example, an accreditation system that is sponsored by a religious institution may have criteria related to its doctrine of faith. Other accrediting bodies may create criteria focused on the management and administration of the program rather than on curriculum and interactions between staff, children, and families.

Controversy

Standards, while based on current research, reflect cultural norms and societal preferences. Definitions of quality and rigor regarding mandatory and voluntary regulation vary by state and professional organizations. Research continues to inform best practice coupled with an ongoing discourse among early childhood professionals and consumers of services over what constitutes valid criteria. For instance, discourse and comparative research regarding the effect of classroom group size on the outcomes for young children continues within the profession.

Over the years, NAEYC has engaged in a process of criteria and system procedure revisions in response to emerging research, feedback from programs engaged in the accreditation process, and consumers. In its first decade, the NAEYC accreditation system criteria garnered criticism for being based on White, middle-class values. Criteria revisions were made in an attempt to address these concerns and create more valid measures of quality. In contrast, some criticize criteria that require programs to support all types of families.

Process

The process of obtaining and maintaining accreditation typically requires programs to complete a series of steps that begins with an application and, if accepted, access to accreditation information and technical support. The next steps typically include program self-evaluation, completion of identified improvements, collection of documentation, verification of practices, and ongoing annual reports documenting continuous quality improvement and ongoing best practices. Time

requirements to complete each step are determined by the accrediting body. Accreditation is awarded for a period of time and at the end of this period the program begins a reaccreditation process.

Application and Self-Evaluation

The application process requires the program to pay an application fee and verify that it meets certain requirements. For instance, a program may be required to meet minimum state health and safety regulations for group care, such as supervision of children, health department regulations, and fire codes, before being accepted to begin the accreditation process. An educator preparation program may need to verify that a certain number of early childhood courses are currently in a degree plan.

After acceptance by the accrediting body, the program follows a process of self-evaluation by identifying strengths and areas of improvement. In order for the self-evaluation process to be successful, it must include all those working in the program and all those served by the program. For instance, in a program serving young children, the teachers, teacher assistants, support staff, administrators, families, and community members would be involved in reviewing and evaluating the program. For an educator preparation program, the team might include administrators, teaching faculty, teacher candidates, graduates, field site representatives, employers, and community members. The accrediting body provides technical assistance and resources for the program during this time of intense analysis and improvement.

During the self-evaluation process, the program sets goals and an action plan for improvement as it strives to meet the accreditation criteria. For instance, an infant toddler program may determine during the self-evaluation stage of the accreditation process that, based on information from family surveys, the staff need to improve communication with family members at departure time. The program may then have a staff meeting to identify ways to improve communication, as well as meet with a family advisory group to seek its input. New communication methods would be implemented, and

follow-up feedback from families would determine if additional changes need to be implemented.

A similar self-evaluation process is followed by an educator preparation program. The program collects and analyzes data regarding student feedback and test scores during the self-evaluation, as well as data from employers and field experience supervisors. In addition, assessment data of learning outcomes is analyzed. During this process, a program might analyze learning outcomes of a teacher candidate's child development knowledge and determine that additional instructional time is needed regarding infant development. The program would identify a specific course and infant development learning outcomes that would be met during the course.

Documentation Collection and Verification

When the self-evaluation process is complete, the program must then document that criteria are met by collecting artifacts and other documentation. During this step of the accreditation process, the program prepares documents as determined by the accrediting body. Documentation and artifacts may include items such as summaries of survey data, lesson plans, syllabi, meeting minutes, financial records, lesson plans, curriculum documentation, and verification of staff qualifications. Each accrediting body provides specific instructions regarding how the documentation and artifacts are to be presented for review. For instance, NAEYC requires programs serving young children to provide classroom portfolios that align documentation to specific criteria, such as documenting how transitions from one activity to another are conducted in a developmentally appropriate manner. CAEP requires a collection of documents, such as syllabi and data charts, that provide empirical evidence.

Documentation demonstrating that criteria have been met is then provided to the accrediting body along with a submission fee. At this point in the process, most accrediting bodies verify that the documentation is complete and that the program is ready for a site visit by a trained professional or a team of trained professionals. Site visitors are

trained to examine documentation, observe programs in action, and ensure reliable results are reported to the accrediting body. Some accrediting bodies review only documentation and do not make a site visit. Reliability of results is critical, because it assures the consumer that the results would be the same regardless of which trained professional is assigned to review the documentation.

After the documentation is reviewed, verified, and/or assessed, the accrediting body determines if the program will be awarded accreditation status. The determination process varies based on the accrediting body and may involve commissioners, a review panel, or staff of the accrediting body to analyze met and unmet criteria reported by the reviewer. Accreditation status indicates that a program meets criteria as determined by the accrediting body. Accredited programs receive a report indicating areas of needed or suggested improvement to be completed during the period of accreditation. Accredited programs are required to submit periodic reports indicating program changes and updates, such as staff changes; improvements as indicated in the initial feedback from the accrediting body; and any other components of a continuous quality improvement plan.

Accreditation Support Projects

Efforts to aid programs seeking accreditation are typically called accreditation support or facilitation projects and vary in the type of assistance provided to programs. Technical support personnel, support groups, and trained mentors often work with programs during the process. Support may also include training, training funds, tuition reimbursement for credit courses, financial assistance for accreditation fees, grants to purchase materials, and resources to support quality improvement.

Accreditation and Regulation of Early Care and Education Programs

In addition to voluntary accreditation systems that assist programs in improving and maintaining quality, early care and education programs must adhere to mandatory regulations that ensure the

health and safety of children in care. Mandatory regulation for programs that serve young children may consist of local, state, or federal requirements that a program must meet to legally operate as a business. These regulations and stringency of monitoring vary by state. For example, one state may require only a high school degree to be a teacher of 4-year-olds, while other states may have more stringent educational requirements. Monitoring visits to verify regulations are being met may occur once a year in one state, whereas visits may be less frequent in another state. Whereas some states have mandatory regulations regarding social, emotional, physical, language, and cognitive learning domains, other states do not require programs to meet regulations beyond basic health and safety.

In contrast to mandatory regulation required to operate an early childhood program, accreditation is a form of voluntary regulation. Early care and education programs have a choice whether or not to pursue accreditation status. Accreditation criteria are typically more stringent than a state's mandatory regulation. For instance, a state regulation may require that no physical punishment be administered by program staff, but accreditation criteria may be more detailed in indicating the developmentally appropriate guidance techniques that staff should implement to help children learn appropriate behavior, such as self-regulation.

Tiered Quality Rating and Improvement Systems

As a strategy to professionalize the field of early childhood, professional development systems (PDSs) began to form in the 1990s to create a professional infrastructure. With the long-term goal of improving care and education for young children by increasing the qualification of teachers, PDSs were created and supported by organizations or governmental programs. Another goal of PDSs was to increase compensation of teachers and reduce turnover. There is wide, research-based consensus in the field that both increased teacher qualifications and reduced turnover play a critical role in improved child outcomes. As part of the PDSs, career ladders and lattices based on education and

experience were created to guide an individual's professional development. Professional development registries were created to maintain a record of a professional's credit and noncredit training. Some accreditation systems play an important role in the effort to professionalize early childhood by requiring higher teacher and administrator qualification than mandatory regulation.

In conjunction with the development of PDSs, quality rating and improvement systems (QRISs) were created to assist early care and education programs to incrementally move from minimal quality, such as meeting only mandatory regulations, to tiered levels of increasing quality and finally achieving accreditation as a top tier of quality. Many states have four levels of quality in their QRIS and require increased teacher qualifications at each level. In addition, most states with QRISs have tiered reimbursement rates for programs that care for low-income children with accredited programs receiving the highest subsidies.

ACQUISITION OF READING AND WRITING

The importance of learning to read and write cannot be overstated. Well-developed literacy skills are associated with improved economic and social outcomes, whereas underdeveloped reading and writing skills correlate with poor economic and social prospects, an increased chance of incarceration, low self-esteem, and even poor health outcomes. To a great extent, the quality of an individual's life depends upon the robustness of his or her literacy skills. Although these skills continue to develop throughout childhood and into

adulthood, the language experiences that children encounter during the early childhood years are critically important in laying a foundation for eventual success in reading and writing. This entry examines the oral language skills that affect the acquisition of reading and writing; the emergent literacy skills that children develop during early childhood; and the types of learning experiences that parents, teachers, and caregivers can provide to promote optimal literacy development.

Oral Language as the Foundation of Literacy

To become proficient as readers and writers, children require a strong foundation of oral language skills. Those skills begin to develop at birth and should be nurtured throughout early childhood. Consider how proficient reading occurs. A reader must look at a sequence of letter-symbols and translate those symbols into spoken words. Without a familiarity with the spoken form of a word, the reader is unable to identify and understand the written form. Reading also implies an understanding of what is read. Comprehension skills are developed in early childhood through rich oral language experiences in which children speak, listen, make inferences, and ask questions. As children grow and develop, so, too, should their oral language skills. Frequent, high-quality, language-rich interactions with adults are important to ensure that children's vocabularies expand and the complexity of their utterances increases over time. Conversations that prompt young children to remember, or imagine, further promote comprehension by developing the abstract thinking skills that are required for reading comprehension in later years.

Proficient writing also requires a strong foundation of oral language skills. Writing is the means by which a writer transcribes a message into symbols for a reader to retrieve at a later time. To construct a coherent message, writers rely on their knowledge of spoken language, including vocabulary and sentence structure, as well as an understanding of how and when language can be used to achieve a specific purpose. To communicate the message, the

writer must record it, breaking up a stream of speech into individual words and transcribing each word into a sequence of letters that corresponds to the sounds heard in speech. This process is easy for proficient writers, who typically do not need to devote conscious attention to it. In fact, however, identifying individual words from an unbroken stream of speech and isolating individual sounds in words presumes phonological awareness, a set of oral language skills that implies the awareness of, and control over, spoken language.

Phonological skills exist on a developmental continuum. Simple phonological tasks include breaking spoken sentences up into individual words, recognizing rhyming patterns, and identifying syllables in a spoken word. Some children enter kindergarten with rudimentary phonological skills, whereas others may have developed more sophisticated skills, including phonemic awareness. Phonemic awareness refers to the ability to hear and manipulate the individual sounds in spoken words.

When writing, young children rely on phonemic awareness skills to listen for and break apart the sounds in the words that they wish to spell. For example, if spelling the word “bat,” children break the word up into the sounds, /b/-/a/-/t/, then use the letters b-a-t to spell the word. This process also works in reverse. Children rely on phonemic awareness skills to sound out words when reading. For example, when reading the word, “went,” children translate each letter into the sound that it represents, “/w/-/e/-/n/-/t/,” then blend the sounds together to identify the word. It is well established that phonological skills, and particularly phonemic awareness skills, are critically important to the acquisition of reading and writing.

Emergent Literacy Skills

Emergent literacy refers to a body of knowledge, skills, and dispositions that children develop prior to being able to read and write conventionally. The concept of emergent literacy acknowledges the importance of language experiences—both oral and written—in early childhood. Further, it presumes that from birth, children are in the process of gradually becoming literate. Emergent

literacy skills include oral language skills, such as vocabulary, oral comprehension, and phonological and phonemic awareness (as discussed in the previous section); knowledge about the functions and forms of written language, including concepts about print and the alphabetic principle; and motivation, persistence, and self-efficacy.

Functions of Written Language

Children who have had frequent and varied reading experiences learn to view reading as a pleasurable activity that provides entertainment and enjoyment. Reading is also a means to obtain information. Children who have observed and participated in writing activities learn that writing is a way to record information, preserve ideas, and communicate.

Concepts About Print: To be effective as readers and writers, children must understand the conventions associated with written language. Over time, through frequent, repeated, and varied exposures to books, children learn how to handle books appropriately; derive meaning from a book by reading the words, not just by looking at the pictures; follow the direction of the print from left to right, top to bottom, and page to page; and distinguish between letters and words. Children also learn that there is a one-to-one correspondence between printed words and the words that are read aloud and that special symbols, called punctuation marks, are used to indicate to a reader when to take a pause and/or when to change tone or expression.

As emerging readers, young children learn to attend to the symbols (letters, words, punctuation) and patterns (the directionality of print, spacing between words) that cue readers as to the meaning embedded in text. As emerging writers, children experiment with those symbols and patterns. Early writing often consists of pictures, scribbles, and/or familiar letters that are repeated or written in seemingly random sequences. Although such writing does not bear a strong resemblance to conventional writing, it nevertheless represents a child’s emerging attempt to communicate a message through writing, and it should be honored as such.

Alphabetic Principle: The alphabetic principle refers to the manner in which sounds in speech are represented by letters. By drawing attention to sounds and letters, adults can encourage children to learn the names and shapes of letters, how to form those letters, and how letters are used to represent sounds. Children's understanding of the alphabetic principle is often reflected in invented spellings. Invented spelling refers to children's early attempts to spell words by writing the sounds that they hear. For example, a child might use the letters "LK" to spell the word "like." These attempts reflect an appropriate, and temporary, stage of literacy development.

Motivation, Persistence, and Self-Efficacy

By observing and participating in a wide range of meaningful and pleasurable literacy-based activities, young children learn to value reading and writing as indispensable tools for leading a happy and productive life. When children enjoy literacy experiences and feel successful in their early attempts, they are likely to be motivated to learn, to persist at tasks for longer periods of time, and to develop self-efficacy, the belief that they are capable of success. Motivation, persistence, and self-efficacy are all important factors that affect how well and how quickly children gain mastery over literacy skills.

Promoting the Acquisition of Reading and Writing

In 1998, the International Reading Association and the National Association for the Education of Young Children adopted a joint position statement that identifies developmentally appropriate practices during the early years (birth to preschool), kindergarten, and the primary grades. Some of these important practices are described here.

The Early Years. Young children require a loving and supportive environment in which to learn and grow. Children are most receptive to learning when they feel happy and emotionally secure. To promote literacy learning, adults can begin exposing

infants to songs and rhymes; games, such as peek-a-boo and pat-a-cake; and developmentally appropriate books, including board books and ABC books. Such literacy experiences should be interactive, developmentally appropriate, and focused on the pleasure of the experience.

During the early years, wide and varied exposure to high-quality books is essential for optimal literacy development. Ideally, young children should be read to several times a day, often when seated in the lap of a loving and attentive caregiver. During reading experiences, children should be encouraged to interact with texts by making predictions and observations, asking and answering questions, and chanting along with familiar or predictable phrases. Post-reading discussions should encourage children to retell favorite events and make connections between the world in which they live and the world of books. Favorite books should be reread as requested. Children of all cultures should be respected and valued and those whose first language is not English should be encouraged to continue to develop proficiency in their first language even as they gain exposure to spoken and written English.

Preschoolers should have easy access to home and classroom libraries that consist of varied and appealing texts. These collections can be supplemented by regular visits to the school or public library. Comfortable, well-lit spaces encourage young children to "pretend read" and explore books independently and with others. A space for writing should be well stocked with writing tools and supplies. Adults should draw children's attention to environmental print, including labels, signs, and logos. Classrooms, in particular, should be print-rich and provide opportunities, spaces, and materials for reading, writing, and dramatic play.

Kindergarten. Literacy instruction in kindergarten should be both active and social and should take into account children's emerging reading and writing skills. In kindergarten, as throughout the early childhood years, adults should deliberately enhance children's vocabularies by reading high-quality books aloud, using interesting words in conversation, and talking about the meanings of new

words. Rereading books multiple times serves to promote increased comprehension. With wide exposure to different types of texts, children begin to notice that different genres, such as stories and informational text, are structured differently and are read for different purposes.

In kindergarten, instruction should emphasize how spoken language can be written down and read back. This objective can be achieved through shared and independent reading and writing, language experience charts, encouraging children to dictate sentences or stories, and providing instruction related to letter names and sounds. In addition, teachers should take care to assess children's phonemic awareness skills so as to provide targeted instruction on an as-needed basis.

The Primary Grades. By the time children reach the primary grades, literacy instruction is more formal and children's reading and writing behaviors more closely approximate conventional reading and writing. Primary-grade students should receive systematic instruction in the alphabetic code so that over time and with practice, they are able to recognize words quickly and accurately, thereby devoting the bulk of their attention to comprehending what they read. Reading instruction should include teaching children how to monitor their own comprehension so that they can recognize when something does not make sense. Children should also be taught how to use strategies deliberately to improve their comprehension (e.g., rereading a particularly dense passage). Writing instruction should begin to emphasize content rather than merely form. Throughout the primary grades, ample opportunities for practicing literacy skills should be provided at home and at school, so that by the end of the early childhood years, children are well on their way to becoming competent, independent readers and writers, capable of learning from texts and expressing their ideas effectively through writing.

ADOPTION

In most contemporary societies, including the United States, family structures are becoming more and more diverse. One such family structure is families that have adopted one or more children.

Adoptive families experience the same joys and challenges of all families. As is the case with other families, adoptive families may have a child with an identified disability and may experience health challenges, financial stress, divorce, and other family struggles. Adoptive parents may be older, single,

gay or lesbian, or in an interracial relationship. But adoptive families must deal with the adoption process itself, and in many cases, adopted children are of a different race, ethnicity, and/or nationality than their parents and siblings. In this entry, the focus is on these two unique aspects of adoptive families.

Quality early childhood programs support adoptive families in two very different ways. First, they acknowledge, embrace, and support the child's unique identity and family context. This includes providing curricular materials, including books, posters, games, and so on, that relate to the child's culture; encouraging adult-child interactions that support the child's identity development; and directly intervening when children and adults use language or engage in behaviors that are destructive or bullying to these children.

The second way quality early childhood programs support adoptive families is by working directly with the adoptive parents. This requires all staff in the program to (a) consult with parents around issues of adoption and racial, ethnic, or national identity, and (b) provide parents with information, resources, support, and guidance regarding their unique family.

Staff in quality early childhood programs understand adoption issues, know about racial, ethnic, and national identity development, are aware of the powerful impact of curricula and peer behavior on identity development, and are informed about resources in the community for families of adoptive children.

Theoretical Perspectives

In understanding young adoptive children and their families, several theoretical perspectives are valid, including Urie Bronfenbrenner's bioecological theory, Jean Piaget's cognitive development theory, Lev Vygotsky's sociocultural theory, and behaviorism.

Bronfenbrenner's theory examines the interrelatedness of all contexts that impact the growth, development, and learning of children. This theory also stresses that when these important ecological contexts work in unison to meet the physical,

social, emotional, moral, and cognitive needs of the child, the child's development and learning are maximized.

Piaget's stage theory is particularly helpful in showing how preoperational children (2 to 7 years old) focus on physical appearance to understand the world, including forming their own identity. The theory relies on a concept known as centrism (limitations in the ability to focus on multiple aspects of the self) to explain the preoperational child's struggle in understanding complex constructs.

Vygotsky's theory details the tremendous impact of the child's social and cultural environment on the child's learning and overall development. Attitudes and behaviors of peers and staff are, therefore, critical.

Finally, behaviorism informs us that behaviors and attitudes that are modeled and reinforced will increase and may eventually become permanent. Thus, how teachers respond to the language and behaviors of peers toward adoptive children in the program, and teachers' own language and behaviors toward these children, is very important. It is critically important to avoid reinforcing stereotypes regarding adoptive children and various racial, ethnic, and national groups to support children's optimal development.

Adopted Children and Developmental Issues

According to the 2010 U.S. Census, approximately 2% of American children are adopted. Parents adopt for a variety of reasons. Highly qualified early childhood staff accept these parents as sincere, dedicated parents, just like other parents they serve in their program. Some adoptions today are what are called open adoptions, where parents and children have some contact with one or more of the birth parents and everyone can access relevant information. However, this is not always possible, especially with international adoptions, where the birth parents are often not known, particularly if the child was adopted from an orphanage.

Some children are infants when adopted; others are older—especially those who are classified as

“difficult to place,” such as children with special needs. More and more adoptive parents are telling their children that they are adopted, usually during the preschool years. Parents expect their child’s early childhood programs to support the position that it is better to tell young children they are adopted. Like all complex constructs, adoption is difficult for a young child to understand, especially when most of the child’s peers are not adopted. By the end of the preoperational stage (about 7 to 8 years of age), most children can appreciate the difference between birth and adoption. During the preschool years, adopted children focus on the positive experience of being adopted—that someone loves them enough to adopt them—and on finding ways to handle differences with their peers and parents. Quality early childhood programs work closely with each parent to determine how they want issues of adoption to be addressed.

During the preoperational stage, children become very aware of physical differences in people, both children and adults. A child who does not look like either parent is going to begin to wonder why he or she does not look like them. Also, these children, similar to biracial children in birth homes who do not look like one or both of their parents, can be greatly influenced when other children and adults express confusion over their relationship to their parents.

Between ages 7 and 11 (Piaget’s concrete operations stage), adopted children begin to realize that their family composition is different from that of most children. They begin to understand that they have birth parents, grandparents, and maybe even siblings somewhere in the world. They wonder why their parents gave them up and whether there was something wrong with them. They may become fearful that their adoptive parent(s) might also give them up. They may become more fearful and often angry. Quality early childhood programs are sensitive to both cognitive and emotional changes in adopted children and work closely with adoptive parents to provide needed resources and to help parents create or join support groups, if desired.

These programs also make sure that any discussions and presentations of the family unit (e.g.,

family doll sets, books, puzzles, content in the curriculum, art, etc.) include adoptive families. Furthermore, the idea that children naturally look like their parents is challenged whenever it comes up, including in visual portrayals of families in the classroom and throughout the center or school. Finally, preschool-age adopted children, like other preschool-age children, typically view their parents as heroes and want to be just like them; in particular, boys want to be like their fathers, and girls like their mothers. Thus, a child from China or Africa who does not look like his or her White adoptive mother or father may express, either at home or in an early childhood program, that he or she wants to look like his or her father or mother. Staff should accept this, and not correct the child; they should also help adoptive parents understand this is natural, appropriate, and healthy.

Racial/Ethnic/National/Cultural Identity

Because of the increased acceptance of unmarried mothers keeping their children, and more minority than White children being placed for adoption, many White adoptive parents in the United States adopt children from foreign countries or U.S. minority children. As of 2015, according to the U.S. Department of State, the countries of origin for the largest number of children adopted by U.S. parents were China, Ethiopia, Haiti, South Korea, and Ukraine. Most of the children from these countries are considered members of racial or ethnic minorities in this country, while the vast majority of adoptive parents are White. This poses a unique challenge for adoptive parents and for early childhood programs, regardless of the racial or ethnic composition of these programs.

Preschool-age children recognize when they look physically different from their parents and their peers. In programs where one race dominates, be it White, Black, Hispanic, Asian, or other, children naturally are curious about a child who does not look like them and does not come from a similar background. These differences can be accepted, embraced, and celebrated through books, activities, learning centers, music and art, visitors to the

classroom, and more. It is important, however, that programs avoid tokenism and a so-called tourist approach to diversity. Tokenism is a minimum effort at integration that involves, for example, having one Black doll, one White doll, one Asian doll, one Hispanic doll, and one Native American doll, which then tends to reinforce stereotypes rather than increasing children's deep understanding of racial and ethnic diversity. An example of a tourist approach would be only highlighting the food and clothing of a child's native country.

Care must be taken when supporting a child's racial, ethnic, national, and cultural identity. The U.S. Census categories, which are used in multicultural texts and training, are not used in most other countries. For example, a Black child from Somalia is not African American, a Maya child from Guatemala is not Hispanic, and a child from Korea has a very different cultural heritage compared to a child from Japan or China. Furthermore, most countries contain within them a rich diversity of racial and ethnic, and sometimes tribal, groups. Thus, a child from Brazil is first and foremost Brazilian, and then maybe Afro Brazilian (Black), Amerindian (indigenous), Middle Eastern, Asian, European, or mixed race (Brazil's official government categories).

Most countries have several social class levels (and in many countries these distinctions are more extreme than in the United States). The initial culture of the adopted child will depend largely on his or her family's social level in the child's home country. Identity development is critically important during the preschool years, and therefore it is important that, to the extent possible, a child adopted from another country is exposed to those in the community from the same nation, culture, and/or ethnic group as the child. At the same time, if the adoptive family is middle class and living in a middle-class community, their children also will be culturally middle-class. Biracial children, no matter what country they come from, require special attention. In many geographic regions or countries, being biracial carries a stigma. Thus, biracial children need help embracing their full mixed heritage in a society fixated on a single race and ethnicity

view of identity. To form a healthy identity, biracial children with a White parent need to be exposed to both their minority heritage and their White heritage in the early childhood program, out-of-school activities, and community events. If the child is a mixture of minority heritages, such as Black and Asian, the child needs to be exposed to both backgrounds. Finally, biracial children need help integrating their full racial identity.

Quality early childhood programs ask adoptive parents how they support their children's healthy identity development. This provides the program an opportunity to work with the family, provide needed resources, and expose other children in the program to diverse racial and ethnic cultures. When seeking experts to work with adoptive children and their families, programs need to make sure that these experts fully understand this unique population. They need to be knowledgeable about the adoption of young children, transracial adoption, and identity development of biracial children. The program can ascertain this by talking to the experts and to parents of the children.

Young children are very adept at learning the language of their new country. However, an early childhood program can include some of a child's home language in the program, which allows the child to teach others and to feel special because he or she knows a foreign language. As the child grows older and becomes curious about his or her home country, language becomes an important part of the child's identity.

AFFORDABILITY

Families need child care and education services for their children for a variety of reasons. Working families, including single parents, need child care for children as young as 6 weeks old to return to work after the birth of a child. Parents may need full- or part-time child care to attend high school or higher education. Other families choose preschool experiences to help children learn social and academic skills before attending public or private elementary schools. Regardless of the purpose of child

care and early childhood education, most settings require families to use a significant portion of their income to pay for it. This entry describes the costs and affordability associated with various types of early care and education options.

Cost of Care and Education

Many families struggle to pay for child care and education for young children. Child Care Aware of America ranks states according to the affordability of child care, based on child care costs and state median incomes. According to the organization, in 2013:

- The average annual cost for an infant in center-based care was higher than 1 year of tuition and fees at a 4-year public college in 31 states and the District of Columbia.
- The cost of full-time center-based care for two children is the highest single household expense in the Northeast, Midwest, and South.
- In the average family budget in the West, only the cost of housing was greater than the cost of child care for two children.

Unlike public education for kindergarten through 12th grade and higher education, early care and education is not widely subsidized by tax dollars. The financial burden for child care rests primarily with families, with some exceptions for families with low incomes. That is why child care represents such a high cost for individual families, despite the fact that child care workers' pay is relatively low, and, according to Child Care Aware of America, as much as 80% of child care business expenses are for payroll and related expenditures. The Bureau of Labor Statistics reported in 2014 that child care workers earn an average of only \$10.44 per hour.

Public support is growing for government, business, and philanthropic groups to financially support early care and education. However, there are still people who believe that children should be at home with their mothers before entering kindergarten and who resist public investment in programs that assist mothers in leaving their children while they are employed outside the home.

For many families, including single parents, there is little choice of whether or not to work outside the home. In every state, according to Child Care Aware of America, the average cost of center-based infant care exceeds 23% of the median income for single parents. A U.S. Census 2013 household economics study reports that parents who are earning minimal pay (earnings below the poverty level) spend 30% of their income on child care costs.

Supports for Families With Low Income

Programs that subsidize the cost of early care and education exist but do not support all of the families that would qualify for assistance. The two primary subsidized programs are the Child Care and Development Block Grant (CCDBG) and Head Start (including Early Head Start).

The CCDBG, a federal program, provides grants to states to subsidize the cost of child care for working families. States then offer funds that assist low-income families to pay for their choice of child care arrangements. Low-income families are defined as families who earn up to 185% of the state median income. Families must also contribute through a co-pay system. Although about 1.7 million children receive assistance through CCDBG, according to 2010 U.S. Census data, these funds only serve approximately one out of every six eligible children, leaving millions of low-income families without financial assistance. Until 2014, the CCDBG had been flat funded since 2002.

Head Start, federally funded since 1965, provides early care and education to more than 800,000 children aged 3 and 4 years. Head Start programs serve children living below the poverty level and children with disabilities. Children in Head Start programs receive comprehensive health, family, and education services. Child Care Aware of America reported in 2014 that Head Start programs serve approximately 40% of income-eligible children.

Early Head Start, added with the reauthorization of the Head Start Act in 1994, serves infants and toddlers through center-based or home-based programs. In 2013, Early Head Start programs

served 150,100 children and 6,391 pregnant women and their families. Early Head Start serves less than 4% of income-eligible children according to Child Care Aware's 2014 report, *Parents and the High Cost of Child Care*. Some Head Start programs only provide care and education for less than half of a typical work day, requiring families to piece together other arrangements if they are employed while their children participate in Head Start programs.

Unintended Consequences of High Cost of Care and Education

Families with young children are typically at the beginning of their careers, with lower salaries, and have less experience making decisions about their children. When facing the high costs of care and education, families may choose other no- and low-cost options to avoid paying for regulated care. These options may include close family members, such as grandparents, but also less familiar family members, neighbors, or acquaintances.

According to 2011 U.S. Census data, 61% of children under the age of 5 are in some type of child care arrangement, with 42% of children cared for by a relative, 33% by a nonrelative, and 12% by both. Less than one quarter of all preschoolers in 2011 were cared for in organized facilities, with child care centers (13%) being more commonly used than nursery schools or preschools (6%). Eleven percent of preschoolers were in home-based care provided by nonrelatives, with 5% cared for by family child care providers.

Caregivers in nonregulated settings have not typically completed background checks, training, and education. Over time, families may be concerned that the caregivers are not meeting their child's needs, reducing working families' confidence in their child care choices. Informal child care settings may also not be reliable or consistent in providing daily care and education.

Although less expensive, informal arrangements may meet the needs of some children and families, these arrangements may cost more when families are not able to work consistently because of the

instability and unreliability of people who provide these services “at will” rather than as an organized business. The impact of lost wages is experienced not only by families but by businesses as well. Child Care Aware of America reported in 2014 that U.S. businesses lose \$3 billion annually because of employee absenteeism as the result of unscheduled child care breakdowns.

The impact of informal child care arrangements on children’s development and learning may not be immediately visible but may emerge as children enter school. The Maryland State Department of Education has found that children who have attended regulated programs enter kindergarten with more skills compared to children who attended informal or unregulated settings.

Quality of Care and Education

Affordable early care and education at any level of quality is not available to many families, especially families living in poverty. Access to affordable high-quality care and education is even more limited. Higher quality care and education requires increases in salary expenses to attract and retain teachers with increased qualifications, provide planning time for teachers and administrators, fund staff for lower child-to-teacher ratios, and provide for ongoing professional development.

Recent public investments in increasing the quality of early care and education have targeted access for children from low-income families. Race to the Top—Early Learning Challenge (RTT-ELC) grants have been awarded to 20 states in three phases since 2011, totaling just over \$1 billion. The purpose of the RTT-ELC program is to help states reach the goal of having all the nation’s children enter kindergarten ready to succeed, with the focus on ensuring that children with the highest needs have increased access to high-quality early learning experiences. The RTT-ELC program identifies children with high needs as those whose families live below 200% of the poverty level (\$46,100 for a family of four in 2012).

States use quality rating improvement systems (QRISs) to assess early childhood program quality

and communicate the level of quality to families. Programs typically receive financial incentives for serving low-income families, and low-income families are encouraged to use subsidy funds with QRIS programs at higher levels.

In December 2014, states that received RTT-ELC funding reported a 43% increase in the numbers of children with high needs enrolled in Child Care and Development Fund (CCDF)–funded programs in the top tiers of their QRIS.

Practices That Affect Affordability

Child care costs to families are highest for children who are infants, up to 1 year old. To maintain a ratio of infants to adults that allows for the individual level of care needed for an infant requires a program to hire more teachers than for the same number of older children. The National Association for the Education of Young Children (NAEYC) recommends a ratio of one adult to three infants, with a group size of six infants and two teachers. Because of the high cost of staffing care for infants, many early care and education programs choose not to serve infants, and those that do must charge higher fees to balance costs. Programs also rely on higher child-to-teacher ratios in preschool classrooms to subsidize the costs related to infant care.

Other countries have implemented protected job leave and financing policies to allow parents to stay home with their infants during the first weeks or months before returning to work. A 2009 study by the Center for Economic and Policy Research reviewed policies in 21 high-income economies. Protected job leave varied across the 21 countries, from only 14 weeks in Switzerland to more than 300 weeks in France and Spain. The United States, with 24 weeks of combined protected job leave for a two-parent family, ranks 20th in the amount of protected job leave available. Financial support for parents is provided by almost all of the countries, typically ranging between 3 months and 1 year of paid leave. The United States is one of only two countries to offer no paid parental leave. Australia also offers no paid leave, but the country financially

supports new parents whether or not they take parental leave.

Financial support for families to care for their own infants has reduced the need for financing group care in other countries. The U.S. Family and Medical Leave Act (FMLA) establishes standards for parental leave but has many loopholes, and only about one fourth of U.S. employers offer fully paid “maternity-related leave” of any duration. In addition to government policies, businesses have an opportunity to support working families to make caring for their own infants an affordable option.

The Future of Affordable Early Care and Education

The affordability of early care and education is now in the national spotlight. During his 2015 State of the Union Address, President Barack Obama announced:

In today’s economy, when having both parents in the workforce is an economic necessity for many families, we need affordable, high-quality child-care more than ever. It’s not a nice-to-have—it’s a must-have. So it’s time we stop treating childcare as a side issue, or as a women’s issue, and treat it like the national economic priority that it is for all of us.

It will take financial and social investments at national, state, and local levels to find affordable early care and education options that meet the diverse needs of U.S. families and their children. At the same time, much more needs to be learned about the elements of quality early care and education that positively impact children and families. It is not enough to have affordable options; children deserve culturally and developmentally appropriate experiences in their first years of life that nurture and stimulate their hearts and minds.

AGGRESSION

The term *aggression* is used to describe angry and hostile acting-out behaviors. While definitions of the term differ somewhat, in the 2012 edition of *Challenging Behavior in Young Children*, Barbara Kaiser and Judy Sklar Rasminsky define aggression as “behavior that is aimed at harming or injuring others.” The authors state, “Challenging behavior isn’t always aggressive . . . but aggressive behavior is always challenging” (p. 13). This entry discusses reasons why young children show aggression, forms and patterns of aggression in

young children, and consequences of the use of aggression for children's development.

As children grow through the preschool years, increasing communication skills and social awareness reduce the need to use aggression during conflicts (expressed disagreements). Young children find the growing ability to put thoughts and feelings into words a powerful tool in social transactions. Along with this positive incentive, their growing awareness that "hurting is wrong," and that children who show aggression get rejected, provides a distinct disincentive. Together the mix of positive and aversive incentives leads to a gradual reduction in the general population of this archetypal challenging behavior.

Still, throughout early childhood some children continue to show pronounced patterns of aggression. In the early years, the child's brain has *plasticity* (the ready ability to build neuron networks in response to experience). During this time, the preschooler is just beginning to form the neuronal architecture in the thinking centers of the brain that allow for *executive function*. Healthy executive function involves abilities regarding the management of impulses, memory activity, cognitive processing, and effective social interaction.

According to research summaries by Megan Gunnar, Adriana Herrera, and Camelia Hostinar, by Roy Lubit and Eileen Giardino, and by Jack Shonkoff and Andrew Garner, children who see their worlds as threatening experience high levels of stress (*toxic stress*). Perceived threat causes brain reactions involving the hormone cortisol that short-circuit the thinking centers involved with executive function. Instead these reactions hyperstimulate the *amygdala* and related parts of the brain that initiate fight, freeze, or flight survival reactions. Children who experience toxic stress show survival-motivated behaviors that frequently include the use of aggression in everyday situations. In such circumstances, normal developmental incentives to move beyond the use of aggression become overwhelmed.

Forms and Uses of Aggression

Two *forms* of aggression in relation to young children are (1) physical aggression, which includes

hitting, kicking, biting, pinching, and similar acts—that is, using physical violence to force one's will upon another, and (2) psychological aggression, which includes verbal assaults, teasing, threatening rejection, ignoring, or otherwise excluding, and so on—using verbal oppression rather than physical force. Anne Williford and Kathryn DePaolis point out that as children grow, physical aggression is more commonly attributed to boys and psychological aggression to girls, although both boys and girls can show either kind, as well as both forms together.

Kenneth Dodge has made a helpful distinction between two *patterns* of aggression: *reactive aggression* and *instrumental aggression*. Reactive aggression is a spontaneous hostile reaction by a child to a perceived imposed threat by another. The child acts out against the other in order to protect himself or herself. The younger the child is, the more likely aggression is to be reactive. Reactive aggression frequently occurs in conflicts over property possession and space encroachment.

An illustration of the use of physical reactive aggression is when a child has Play-Doh that another takes. The first child pulls the other's hair, hits, or pinches in a reaction to the incursion. An example of psychological reactive aggression is a child walking in line who gets his heel accidentally stepped on. He wheels around and yells at the child behind him, "Don't do that, you butthead!"

Concerning the patterns of use, instrumental aggression often is the more vexing for adults who care for young children. Children who show instrumental aggression usually have not lost control of emotions. They use aggression intentionally to achieve a goal. The goal may be obtaining a particular object, gaining a desired privilege, or oppressing another in order to force subservience (i.e., bullying). An example of physical instrumental aggression is an older child forcibly removing a younger child from a tricycle so the older child can ride. An example of psychological instrumental aggression is an older child announcing to another that he or she is too "little" to complete a puzzle—a puzzle that happens to be the favorite of the older child, who has just arrived at the puzzle table.

With instrumental aggression, the child is not just reacting defensively to a perceived threat. Instead, the child is acting to achieve a goal that he or she perceives is being blocked by the threat. Williford and DePaolis point out that instrumental aggression involves not only brain operations that are threat-based but also operations that are pleasure-seeking. Key here is that both types of aggression, and not just reactive aggression, arise from toxic stress in the brain. Both types of aggression are symptoms that children are experiencing stress levels beyond their ability on their own to manage in healthy ways. In an unfortunate sense, instrumental aggression is testimony to the learning capabilities of young children even when they are living with toxic stress.

Consequences of Use of Aggression

Any child might try instrumental aggression on an experimental basis. For a statistically small number of children, however, patterns of instrumental aggression become ingrained. Instrumental aggression becomes an ongoing survival strategy. These children learn, in the presence of a threatening world, that the use of instrumental aggression might be successful in achieving their aims. Even if not, the consequent conflict, which often involves an adult, results in an adrenalin hormone rush that for a while masks the cortisol-induced stress that motivated the instrumental aggression in the first place.

One traditional approach to both patterns of aggression has been to presume the child is being “bad” and punish in order “to shame” him or her into being “good.” The problem with this approach is that punishment tends to keep the child’s stress at toxic levels and makes healthy executive functions more difficult to learn. The dynamics of early brain development mean that the young child lacks the resources on his or her own to deal with the stress in ways other than a continued show of aggression. A cycle of

Stress that leads to conflict involving aggression
Accompanied by an adrenalin rush
Followed by punishment and rejection by others
Leading to sustained stress

is not one adults should reinforce in young children.

Gunnar, Herrera, and Hostinar conclude that reinforcement of this cycle in a young child can lead to a significant long-term degradation of chances for social-emotional health and educational and vocational success. Unless adults build relationships with children that create trust, reduce stress, and teach socially responsive resiliency skills, these children suffer lasting difficulty with brain development in relation to healthy executive function, constructive social relations, and fundamental mental health.

ALLIANCE FOR CHILDHOOD

The Alliance for Childhood began in Europe in 1998 and in the United States in 1999 when educators and health professionals met out of a deep concern for the decline in children's health and well-being. Its goal was to highlight the profound value of childhood as well as its vulnerability. Its projects bolster the healthy essentials of childhood, which include relationships with caring adults and with nature, creative play and the arts, hands-on experiences, and a sense of the sacred. Its publications and educational campaigns have focused on the need to restore creative play to childhood and to reduce the overuse of screen time in childhood, which interferes with so many of the healthy essentials. The Alliance partners with many organizations and individuals to promote policies and practices that support children's healthy development, love of learning, and joy in living.

Childhood as a Whole

At its founding meeting the participants shared their deepest ideals about childhood. Their words were then woven together into a verse that ends with these lines:

The spirit of childhood calls for protection and nurture.

It is an essential part of every human being

and needs to be kept alive. (Alliance for Childhood, n.p.)

As of early 2015 the Alliance was working on two international endeavors to strengthen childhood as a whole. One is the Decade for Childhood: 2012–2022, which is spearheaded by the Association for Childhood Education International, which organizes a summit on the state of childhood every two years. The Decade for Childhood highlights the problems associated with poverty, abuse, and neglect, as well as those associated with the high-pressured lives experienced by many children today regardless of their socioeconomic background. The U.S. Alliance is also part of an international working group with its partners in Europe and Brazil that organizes international conferences from time to time.

A Critical Look at Computers in Education

In addition to focusing on childhood as a whole, the Alliance for Childhood works on specific areas of concern. Its first report, *Fool's Gold: A Critical Look at Computers in Education*, received worldwide media coverage. It raised the question of why U.S. schools were devoting so much time and money to computer-based learning when there was no evidence that it made a significant positive difference in the education of children. It was published in 2000; the same question can be asked today, for there is still little evidence that computers in early education and elementary schools enhance the quality of education or improve its outcomes, compared to investing in sound teaching approaches that integrate the arts and foster curiosity and creativity.

The Alliance for Childhood has continued its focus on digital technology in early education by partnering with two other organizations to write a 2012 report, called *Facing the Screen Dilemma: Young Children, Technology and Early Education*,

summarizing studies about screen time. It discusses ways to include screens in early childhood settings, as well as reasons to teach without them.

Restoring Play to Childhood

In 2005 the Alliance began a campaign to restore child-initiated play in neighborhoods, schoolyards, and early childhood settings. Play was no longer valued and children were given little time for it. Instead, their days were filled with organized activities, large amounts of screen time, and increasing amounts of homework. Parental fears kept children indoors, and some neighborhoods—even perfectly safe ones—looked like ghost towns. No longer did bands of children roam the neighborhood, playing on the sidewalks or in local parks.

Gradually, with the help of major media coverage about the value of play, and the work of the Alliance and other organizations, such as KaBOOM!, the mind-set about play has changed. Surveys now indicate that most parents want their children to play more frequently but are not sure how to accomplish it, for they want some degree of supervision. For this reason the Alliance turned to the adventure playgrounds of Europe and California as models of challenging, well-rounded play spaces. Here elementary-age children, in particular, play freely in the presence of staff often called playworkers. They are well educated in play for all ages and lend support to children's play without dominating or directing it.

To educate the public and professionals about play and playwork, the Alliance has developed publications, videos, and fact sheets, and has offered many workshops. It has recently focused on the role of risk in children's play and the benefits of dealing with age-appropriate risk in childhood. When children are faced with risk they rise to it, using their innate sense for risk assessment.

Adults' fears of injury and liability serve as a major deterrent to children's freedom to play. Yet studies of adventure playgrounds, which offer children as much risk as they can handle, found that accident rates were relatively low, that there were few lawsuits, and that insurance companies

considered them to be no more dangerous than swimming pools or other activities run by parks departments.

Enhancing Play-Based Experiential Learning in Early Childhood

The Alliance is strongly focused on the need for play-based experiential education in preschool and kindergarten. Children of these ages are naturally inclined to absorb content offered in experiential ways, especially when combined with time for child-initiated play. Yet these proven approaches have been largely replaced by didactic instruction in kindergarten, including time spent with worksheets and even scripted curricula. These new approaches have not been shown to yield long-term gains. The pressure to prepare children for current kindergartens—where they are expected to read and perform in other ways previously associated with first grade—means that preschools are being pressured to become more instructional and less experiential. As a result, there is growing concern about serious behavioral difficulties beginning in preschool and especially affecting boys, who find it very difficult to sit still and concentrate for large amounts of time at this age.

The Alliance for Childhood has published articles and reports on the value of play-based experiential learning in preschool and kindergarten, including a 2015 paper titled *Reading Instruction in Kindergarten: Little to Gain and Much to Lose*. As of early 2015, it was developing a digital resource with videos on this subject. This resource will be freely available, along with other Alliance publications, on its website.

AMERICANS WITH DISABILITIES ACT

In 1990, the Americans with Disabilities Act (ADA) was passed in an effort to stop discrimination against people with disabilities. For the purposes of the ADA, a person is considered to have a disability if he or she

- has a physical or mental impairment that substantially limits one or more major life activities,
- has a history of such an impairment, or
- is regarded as having such an impairment.

Unlike the Individuals with Disabilities Education Act (IDEA), which functions to provide a free and appropriate public education for individuals ages

birth to 21, the ADA provides these protections across the entire life span. The act is subdivided into five parts referred to as “titles.”

Title I: Employment

Title I of the ADA was written to prevent discrimination of people with disabilities at work. This law applies to private employers who have more than 15 employees, state and local government agencies, labor unions, and employment agencies. According to Title I, no employer can discriminate against qualified job applicants because the applicant has a disability.

In addition, Title I makes it illegal to ask a person about his or her disability during the employment interview. However, potential employees may choose to discuss their disability and ask for accommodations that will enable them to perform the functions of a particular job. Such accommodations may include equipment modifications such as adaptive keyboards or a specific type of desk that is fitted for a wheelchair. Title I further states that an existing employee with a disability may ask for reasonable accommodations while at work.

Once an accommodation is requested, the employer and the employee should discuss the individual's needs and identify an appropriate reasonable accommodation. However, if the requested accommodation creates an undue hardship on the employer, the employer may look for another accommodation instead or, in some cases, may opt not to provide any accommodation. The employer may also choose the least costly accommodation in the event that one of several possible accommodations is needed.

Other aspects of Title I are as follows:

- It is unlawful for an employer to ask job applicants about their disability including the extent, severity, or medical aspects of that disability. An employer may ask job applicants if they are able to perform certain aspects of the job. In addition, the employer may conditionally offer an applicant a job based on the results of a medical exam, but can only do so if such an

examination is required of all employees doing the same or a similar job.

- Medical records, medical exams, and requests for accommodations are to be kept confidential.
- Drug and alcohol abuse are not covered by the ADA. Testing for use of illegal drugs and/or alcohol is not subject to the confidentiality rules for other types of medical records.

Title II: Equal Access

Title II covers activities and programs of all state and local governments and mandates that they provide people with disabilities an equal opportunity to benefit from and participate in all of their programs, services, and activities. This includes public education, employment within the government, transportation services, parks and recreation activities, health care such as state and local health departments, social services, courts, voting, and town meetings.

Under Title II, state and local governments are required to make specific accommodations to buildings. This applies to both new construction and alteration of older buildings. In very old buildings where such alterations cannot be made, programs must be relocated to facilities that offer appropriate accessibility and accommodations.

Public transportation is also included under Title II of the ADA. All bus and railroad cars must be accessible, and any new bus or train station must be designed to be accessible for persons who have disabilities. In the event that public transportation cannot be made accessible, other types of transportation must be provided. Modes of transportation that are covered include buses, commuter transit, subways, and intercity rail systems. Housing is not covered under the ADA unless it is a housing project that receives federal or state funds. Federal and state organizations are required to comply with the ADA.

Title III: Architectural Barriers

Title III of the ADA is the portion of the law that most directly impacts young children with developmental delays and is discussed in detail later in this

entry. Under this provision, all places that service the public, including restaurants, theaters, schools, medical facilities, and child care facilities, must be made accessible to persons with disabilities. That means that whether the building is new construction or has been in use for many years, barriers must be removed. For example, if a building has multiple stories, an elevator or lift must be constructed. Restroom facilities must provide a wheelchair-accessible bathroom, and hotels must maintain rooms that are designed for persons with disabilities. This also applies to places such as libraries, museums, and parks. Many state and national parks have gone a step further and now provide wheelchair-accessible playgrounds that include special swings that accommodate wheelchairs.

Title IV: Telecommunications

Title IV covers telephone and television access for people with hearing and speech disabilities. The law mandates that telephone companies establish a specialized relay service that operates 24 hours a day, 7 days a week. This relay service must enable people with hearing and speech disabilities who use special equipment to communicate with each other using a communications assistant. This equipment is called a TTY or a TTD. TTD stands for text telephone for the deaf. While these two terms are used interchangeably, the more accepted term is TTY which stands for text telephone. Title IV also requires closed captioning of public service announcements that are federally funded.

Title V: Miscellaneous Provisions

According to Title V of the ADA, individual states and Congress are covered by the ADA. In addition, it provides for repayment of legal fees for successful proceedings related to the ADA and establishes a system for technical assistance. The Civil Rights Division of the U.S. Department of Justice offers education and technical assistance through a variety of ways designed to encourage voluntary compliance with the ADA. Activities it provides include direct technical assistance and education to the public through the ADA website

and the ADA information line, developing and disseminating technical assistance materials to the public, and undertaking outreach projects.

Additionally, Title V includes a provision prohibiting threats or retaliation against people with disabilities or those attempting to aid people with disabilities in asserting their rights under the ADA. This means that in most states, even though the Eleventh Amendment has been interpreted as barring individuals from suing state agencies in federal court, state agencies can be sued to make buildings and workplaces accessible to those with disabilities. The law also protects persons with disabilities who are successful in a lawsuit related to ADA from being harassed or threatened in any manner by the parties being sued. It also allows judges to use their own discretion with respect to reimbursement of attorney fees as part of a settlement in a successful lawsuit.

Amendments

On September 25, 2008, amendments to the ADA were signed. These amendments detail more clearly who is covered by the civil rights protections of the ADA. They also broaden the definition of “disability” to include impairments that substantially limit a major life activity. Additionally, the amendments state that when deciding who qualifies as disabled, one cannot take into account assistive devices, accommodations, medical therapies, and supplies. Finally, the amendments also address periodic events or disabilities that may go into remission but that can still significantly limit a major life activity, like epilepsy and post-traumatic stress disorder (PTSD).

Americans with Disabilities Act and Child Development Centers

Almost all child care centers, regardless of their size or number of employees, must comply with the ADA. Title II (equal access) and Title III (architectural modifications) of the ADA have the most impact on child care centers. Even small, home-based centers that may not be required to follow some state laws are required to comply with Title III. Child care services provided by government

agencies, such as Head Start, summer programs, and after-school programs, must comply with Title II of the ADA. Both titles apply to how the center interacts with and provides services to children, parents, and guardians.

Child care centers that are affiliated with and managed by religious entities such as churches, mosques, or synagogues do not have to meet the provisions of the ADA. However, this does not apply to private child care centers that are operating on the premises of a religious organization. In other words, if a child care program is on the grounds of a religious organization but not operated by the religious organization, Title II and Title III apply to the child care program but not to the religious organization. For example, if a private child care program is using the facilities of a church, pays rent to the church, and has no other connection to the church, the program has to comply with the ADA.

The ADA requires that child care providers not discriminate against persons with disabilities on the basis of disability; they must by law provide children and parents with disabilities with an equal opportunity to participate in the child care center’s programs and services. In addition, child care centers cannot exclude children with disabilities from their programs unless their presence would pose a direct threat to the health or safety of others or require a fundamental alteration of the program. Examples include the following:

- Centers have to make reasonable modifications to their policies and practices to include children, parents, and guardians with disabilities into their programs unless doing so would constitute a fundamental alteration to the program.
- Centers must provide appropriate auxiliary aids and services needed for effective communication with children or adults with disabilities, when doing so would not constitute an undue financial burden.
- Centers must make their facilities accessible to persons with disabilities. Existing facilities are subject to the readily achievable standard for barrier removal, while newly constructed facilities and any altered portions of existing facilities must be fully accessible.

Directors of child care centers cannot just assume that a child's disabilities are too severe for the child to be enrolled in the center's program. In order to deny admission, an individualized assessment by qualified personnel must be completed, and a determination must be made that the program in question cannot meet the particular needs of the child without fundamentally altering its program. In conducting this assessment, the evaluator must not react to preconceptions, generalizations, or stereotypes about what children with disabilities can or cannot do, or how much assistance they may require. Instead, the caregiver should talk to the parents or guardians and any other professionals (such as educators or health care professionals) who work with the child in other settings. Providers are often surprised at how easy it is to include children with disabilities in their programs.

There are a few other exceptions to the ADA. Child care centers that are currently enrolling children are not required to accept children who would pose a direct threat to other children or whose presence or necessary care would fundamentally alter the nature of the child care program. If an insurance company charges higher rates to a center serving children with disabilities, that is not considered a fundamental alteration of the program. Instead the extra cost should be treated as overhead and divided equally among all paying customers. However, if the center has a waiting list, Title II does not require providers to move children with disabilities to the top of the list.

On the other hand, a center may not reject a child because the child requires individualized instruction. If a child needs extra help and attention due to a disability and can be included without fundamentally altering a child care program, the child must be accepted. For instance, if parents enroll a child with autism spectrum disorder who requires a personal assistant, and that assistant will be provided at no cost to the child care center (usually by the parents or through a government program), the child cannot be excluded from the program. Any modifications necessary to include such a child must be made if they are reasonable.

This is not to suggest that all children with autism require a personal assistant in order to be successful in a child development center. To make this determination, an individualized assessment is required. However, the ADA generally does not require centers to hire additional staff or provide assistance to a particular child with a disability.

Other exceptions to Title III include a child with behavior issues who poses a serious threat to others. A serious threat is defined as a significant risk of serious harm to the health and safety of others, including children and adults. The determination that a child poses a threat may not be based on generalizations or stereotypes about the effects of a particular disability; it must be based on an individualized assessment that considers the particular activity and the actual strengths and weaknesses of the child.

To find out whether a child has a medical condition that poses a significant health threat to others, child care providers may ask all applicants whether a child has any diseases that are communicable through the normal types of incidental contact expected to occur in child care settings. Providers may also inquire about specific conditions, such as active infectious tuberculosis, that in fact pose a direct threat. Centers cannot exclude a child solely because he or she has human immunodeficiency virus (HIV) or acquired immunodeficiency syndrome (AIDS). There has been significant research that indicates that HIV, the virus that causes AIDS, cannot be easily transmitted during the type of personal interactions indicative of child care centers. Children with HIV or AIDS generally can participate in all aspects of a child care program. Universal precautions, such as wearing latex gloves, should be implemented whenever caregivers come into contact with blood or bodily fluids, such as when they are cleansing and bandaging playground wounds or when changing diapers.

Centers that provide personal services such as diapering or toileting assistance for young children must reasonably modify their policies and provide diapering services for older children with disabilities who require it. Generally speaking, centers that diaper infants should diaper older children with

disabilities as long as they do not have to leave other children unattended to do so.

A determination must be made whether it is a reasonable modification to provide diapering for an older child who needs diapering because of a disability when the center does not normally provide diapering for other children. Before making that decision the following should be considered: (a) whether other typically developing children need occasional toileting help when, for example, they have accidents; (b) whether providing toileting assistance or diapering on a regular basis would require a child care provider to leave other children unattended; and (c) whether the center would have to purchase diapering tables or other equipment to offer such services to the child. However, if a parent or personal assistant (not funded by the child care center) is available to do the diapering, then the center cannot exclude the child with disabilities.

Other issues covered by the ADA include the following:

Pets. Even if a program does not allow pets, it is required to allow a child with a service animal to bring that animal to class with him or her.

Medication. In some circumstances, it may be necessary to give medication to a child with a disability in order to make a program accessible to that child. Although some state laws may differ, as long as reasonable care is used in following written instructions from the doctor and parent or guardian about administering medication, centers should not be held liable for any resulting problems. Providers, parents, and guardians are urged to consult professionals in their state whenever liability questions arise.

Allergies. Children cannot be excluded based on diagnosed allergies. Such allergies might include severe reactions to bee stings or certain foods. A center needs to be prepared to take appropriate steps in the event of an allergic reaction, such as administering a medicine called epinephrine that will be provided in advance by the child's parents or guardians.

Diabetes. Children with diabetes can usually be enrolled in a child care program without fundamentally altering the program. Providers should obtain written authorization from the child's parents or guardians and physician, and follow their directions for simple diabetes-related care. In most instances, they will authorize the provider to monitor the child's blood sugar (blood glucose) levels before lunch and whenever the child appears to be having certain easy-to-recognize symptoms of a low blood sugar incident. The child's parents or guardians are responsible for providing all appropriate testing equipment, training, and any special food necessary for the child.

Prosthetic Devices. Some children with mobility impairments may need assistance in taking off and putting on leg or foot braces during the course of a day. As long as doing so would not be so time consuming that other children would have to be left unattended, or so complicated that it can only be done by licensed health care professionals, it would be a reasonable modification to provide such assistance.

Even if there are no children with disabilities currently enrolled in a center, that center has an obligation to remove barriers to access for people with disabilities. Existing privately run child care centers must remove any architectural barriers that limit the participation of children with disabilities (or parents, guardians, or prospective customers with disabilities) if removing the barriers is easily accomplished and can be carried out without much difficulty or expense. Installing offset hinges to widen a door opening, installing grab bars in toilet stalls, or rearranging tables, chairs, and other furniture are all examples of barrier removal that might be undertaken to allow a child in a wheelchair to participate in a child care program. Centers run by government agencies must ensure that their programs are accessible unless making changes imposes an undue burden; these changes will sometimes include changes to the facilities.

Newly constructed, privately run child care centers (designed and constructed for first occupancy after January 26, 1993) must be completely

accessible to and usable by individuals with disabilities. This means that they must be built in strict compliance with the ADA Standards for Accessible Design. New centers run by government agencies must meet either the ADA standards or the Uniform Federal Accessibility Standards.

According to information provided by the U.S. Department of Justice (Civil Rights Division), to assist businesses in complying with the ADA, Section 44 of the Internal Revenue Service (IRS) Code allows a tax credit for small businesses, and Section 190 of the IRS Code allows a tax deduction for all businesses. The tax credit is available to businesses that have total revenues of \$1,000,000 or less in the previous tax year or 30 or fewer full-time employees. This credit can cover 50% of the eligible access expenditures in a year up to \$10,250 (maximum credit of \$5,000). The tax credit can be used to offset the cost of complying with the ADA, including, but not limited to, undertaking barrier removal and alterations to improve accessibility, providing sign language interpreters, and purchasing certain adaptive equipment.

Three precedent setting cases helped clarify the ADA guidelines in regard to child care facilities.

Diapering. A complaint brought to the Disability Rights Section of the Civil Rights Division of the Department of Justice on behalf of a child cited that a child care facility did not meet the guidelines of ADA. As a result, the Sunshine Child Center in Gillett, Wisconsin, agreed to (a) provide diapering services to the child requiring more frequent diapering than his typically developing peers, (b) provide assistance with prosthetic devices as needed, (c) enroll the child based on chronological rather than developmental age, (d) remove all physical barriers, and (e) design and construct its new facility to be accessible to all children with disabilities.

Diabetes. In 1996, the Department of Justice entered into a settlement agreement with KinderCare Learning Centers, which at the time was the largest chain of child care centers in the country, to provide appropriate care for children with diabetes. This care included providing finger-prick blood glucose tests to a child when needed. In 1997, La Petite

Academy—the second-largest chain at the time—agreed to follow the same procedures.

Allergies. La Petite Academy, in an agreement with the Justice Department signed in 1997, agreed to keep epinephrine on hand to administer to children who have severe and possibly life-threatening allergic reactions to foods or bee stings and to make alterations to some of its programs so that children with cerebral palsy can participate.

The Department of Justice operates an ADA information line where information specialists are available to answer general and technical questions about the law, including how it relates to services and programs provided by child care centers. It also provides a 24-hour automated service for ordering ADA materials and an automated fax-back system that delivers technical assistance materials to fax machines or modems.

ANTI-BIAS EDUCATION, COMPONENTS OF

Anti-bias education is a developmentally appropriate, culturally responsive and social justice approach developed for early childhood programs. Although anti-bias education includes children's curriculum, it is not in and of itself a curriculum. Rather, similarly to developmentally appropriate practice, anti-bias is a lens for assessing and modifying the entire children's program: program policies and approaches, staff relationships, partnerships with families, environment, classroom management, and children's curriculum. In each of these arenas, anti-bias thinking includes how the full program supports children and families' social identities and all forms of human diversity; addresses issues of inequity and bias; and empowers children and the adults who care for them to create an equitable, respectful program.

As stated in *Anti-Bias Education for Young Children and Ourselves*, published by the National Association for the Education of Young Children, an anti-bias perspective considers the following:

Administration. Do the school's formal and informal policies name and respect the range of families, cultures, and abilities within the community? (For example, Are letters home addressed to "Dear Parents," which implies two parents only, or to "Dear Families," which includes single parents, grandparent-led families, etc.?)

Staff. Does the program have a diverse staff in terms of gender, racial identity, culture, and so forth? Does staffing reflect or contradict the dominant culture patterns of White people in charge and people of color in secondary roles? Does staff development include exploration of social identities and covert and overt bias?

Families. Are all families made visible in the learning environment and in all program documents? Does staff consult families regarding their values, identities, needs, and hopes for their children? Is the family an active participant in the program's planning and self-assessment?

Classroom Management. Do classroom expectations of behavior avoid stereotypes regarding gender, culture, and racial identities? Do forms of behavior management support children's identities, sense of self, and sense of belonging? Are family members seen as resources to understand (rather than as causes of) their children's behavior and responses?

Environment. Are all children, families, and staff equally and accurately visible in toys, books, wall decorations, photographs, and other materials? Are further aspects of diversity also introduced?

Curriculum. Does the curriculum support a balance of teacher planning and the openness to unexpected "teachable moments" that emerge from the children? Does the curriculum utilize the four core anti-bias goals covering identity, diversity, fairness/unfairness, and action?

Culture, Language, and Fairness

Every child and every family has a culture. So, too, does every early childhood program. The degree to which the program culture honors and incorporates the child's culture lessens the hurtful impact of culture shock upon the child.

A culturally responsive program sets the following goals for all children:

1. Children will feel pride in and will have the language to express their family's cultural identity, traditions, and heritage.
2. Children will use their home culture knowledge in the group setting, as they also learn to thrive in the culture of the school and larger society.
3. Children will continue to develop in their home language, while also learning to be bilingual.

4. Children will demonstrate curiosity, enjoyment, ease, and empathy with cultural differences and similarities.
5. Children will identify disrespectful interactions and learn to interact respectfully regarding cultural differences.

Addressing the topics of culture, language, and fairness requires staff to understand the differences between surface culture (holiday foods and costumes, artifacts, etc.) and deep culture (all the deeply held beliefs, values, and history of a family). It is vital to pay attention to the lived experiences of real families rather than to stereotypes about groups of people. Staff must also have knowledge of bilingual language development and the close, positive link between cognitive growth and use of home language. Empathetic awareness of the particular challenges new immigrant families and children face as they enter early childhood programs is also necessary.

Racial Identity and Fairness

Race is not a biological reality. It is a social construct that continually evolves as the society changes. Every person living in a society with a history of racism has a prescribed racial identity impacting how all people are perceived and treated by the institutions of their society, as well as by other members of the society. This aspect of social identity continues to be one of the most contentious, confusing, and painful aspects of U.S. society. Consequently, confusion and tension are often the rule for early childhood programs addressing (or trying to avoid addressing) racial identity and racist bias.

The goals for children on this topic are the following:

1. Children will have accurate information about and feel comfortable with their physical characteristics linked to racial identity.
2. Children will feel positive but not superior about their racial identities.
3. Children will appreciate their shared human physical characteristics and will have accurate information about and respect for each other's individual physical characteristics.
4. Children will demonstrate appropriate skills for identifying and challenging misinformation and stereotypical ideas about "race."
5. Children will develop nonbiased responses to racial differences and will demonstrate beginning skills for interrupting biased behaviors and for creating a fair classroom environment.

Staff needs to learn to name and understand the impact on them of their own racial identities, as well as their attitudes toward other racial identities. They must listen carefully to how families racially self-identify, what they have and haven't discussed with their children, and what terms they want their child to use. It is helpful for children (and families) to discuss how interesting (and positive) it is that we are all alike in our humanness and yet all different in our physical characteristics. As many racist behaviors are subtle and unconscious, it is particularly important for staff to listen carefully to what families say they or their child experience and to include that information in staff development and planning.

Gender Identity and Fairness

Gender identity includes both gender anatomy (biology) and gender role (social expectations). These are the earliest social identities most children articulate. Many adults are oblivious to the continual instruction children receive about what it means to be a boy or a girl. These messages tend to confuse gender anatomy (e.g., our bodies) with socially proscribed gender behaviors, which many incorrectly treat as innate.

The following goals regarding gender identity and fairness reflect the early childhood principle of fostering all children's fullest range of abilities and skills.

1. Children, regardless of gender, will participate in a wide range of activities necessary for their full cognitive and social-emotional development.
2. Children will demonstrate positive feelings about their gender identity and develop clarity about the relationship between their anatomy and their gender role.
3. Children will talk about and show respect for the great diversity in appearance, emotional expressiveness, behavior, and gender roles for both boys and girls.
4. Children will recognize unfair or untrue messages (including invisibility) about gender roles.
5. Children will practice skills for supporting gender role diversity in their interactions with peers.
2. Children will appreciate that material possessions do not define them or anyone else and that all people are valuable regardless of their material possessions.
3. Children will be aware of the many kinds of work that family members do, paid and unpaid, both in the home and in the wider world.
4. Children will recognize unfair or untrue messages (including invisibility) about children and families based on their economic status.
5. Children will stand up for themselves and others against teasing or rejection based on economic status.

Active, intentional nonsexist curriculum and classroom management are essential for children's healthy development. This includes thoughtful attention to staffing that includes men as key members of the team, without narrow assignment of tasks based on stereotypical gender roles. It also requires thoughtful attention to and negotiation of cultural differences regarding gender roles.

Economic Class and Fairness

Economic class is one of the least recognized, although one of the most impactful, aspects of family life and children's experiences. It also silently separates staff members within children's programs. Class shame or discomfort sets in early. Children, ever sensitive to the unspoken feelings of the adults in their lives, absorb a wide range of assumptions about the value of their families (and therefore themselves) based on tangible (who has new "stuff" and who doesn't) and intangible (which families "fit in" with the teachers) experiences.

The goals for children are the following:

1. Children will feel pride in their family's efforts to care for them and provide a living, regardless of the family's economic conditions.
2. Children will learn and practice language and actions to resist hurtful or biased messages about their own and others' families.

Family Structures and Fairness

Family is central to the life of every child. It is through this earliest relationship that children come to view themselves and find their place in the world. The structures of the family (who its members are) are highly varied, and many children will experience changes in their family structure during different times of their lives. Early childhood programs are one of the first places where children learn whether or not they and their family are acceptable, "normal," or respected.

The goals for children are the following:

1. All children will have language to define their own family from their personal experience and will see their family represented in the learning environment.
2. Children will develop awareness and appreciation of different kinds of families beyond their own as well as the ability to talk comfortably about their own and others' families.
3. Children will develop skills to recognize and question unfair comments or depiction of families, including invisibility, whether from children, media, or adults.
4. Children will learn and practice language and actions to resist hurtful or biased messages about their own and others' families.

Different Abilities and Fairness

All children are in a state of being and becoming at the same time. They are aware of their own limitations, struggles, and desire to accomplish. They view the range of ability as interesting and curious. When adults model for and help children to see others (and their selves) as fully human, complex people, then disabilities become one more aspect of the person, not the definition of who they are.

The goals for children around this topic are listed here:

1. All children will develop autonomy and independence (as they are able), as well as confidence and pride in their competence.
2. All children will learn accurate information, appropriate to their developmental stage, about disabilities and special needs.
3. All children will gain understanding about how their own abilities are the same and different from others.
4. All children will learn to interact knowledgeably, comfortably, and fairly with each other, whatever their abilities.
5. All children will learn how to challenge name-calling and stereotyping with respect to their own or others' abilities and will share ideas about accessibility in order to promote rich interaction and independence.

Staff should clarify with families what terms they use with a child to discuss her or his disabilities and work closely with families on the best ways to support them and their child within the program.

Holidays, Celebrations, and Fairness

Holidays are often highly significant events in the lives of children and families. They may embody deeply held religious beliefs (e.g., Easter, Ramadan, Yom Kippur), highlight historic societal events or people (e.g., Independence Day, Martin Luther King Jr. Day), ritualize important family and life passages (weddings, birthdays, funerals), or mark

the passage of the year for institutions (annual picnic, family potluck, graduations).

Some programs teach *about* holidays, and some celebrate them. Either way, how holidays are presented is one of the key ways children come to understand the degree to which their family is acceptable or marginalized and one of the key ways they come to see “their way” as the one “right way.”

How holidays are handled can trivialize important religious beliefs or present a sociopolitical view that negates the experience of families and their cultural histories. Even when families share the same general religious orientation, there is always a great range in how they express those beliefs and celebrate their doctrines. Conversely, holidays that are invisible in early childhood programs send the message that they don’t belong in the school culture, thus marginalizing families and children.

An anti-bias approach to holidays strives to support children reaching the following goals:

1. Children will see their family’s approach to holidays honored and understood in their early childhood program.
2. Children will become aware of, and be comfortable with, the reality that people happily celebrate the same holiday in different ways or celebrate different holidays entirely.
3. Children will learn that some people do not celebrate religious or national holidays but have other ways of having family celebrations and traditions.
4. Children will recognize misinformation and stereotypes associated with specific holiday traditions.
5. Children will participate in celebrations that honor people’s work for fairness and justice for all people.

ANTI-BIAS EDUCATION THEORY

An anti-bias approach puts diversity and equity goals and practice at the center of all aspects of a program's organization and daily life. Children's developing identities and their questions, observations, and ideas about diversity and bias are an integral part of the daily curriculum. The four core learning goals of anti-bias education are designed to foster accurate, positive social identities in children, while either preventing or mitigating the harm caused by institutional and individual misinformation, stereotyping, prejudice, and discrimination. They are meant for children of *all* social identity groups and apply to all the many kinds of human diversity. Each goal interacts with and builds on the others. As stated in *Anti-Bias Education for Young Children and Ourselves*, published by the National Association for the Education of Young Children, the core goals state that each child will do the following:

- Demonstrate self-awareness, confidence, family pride, and positive social (group) identities.
- Express comfort and joy with human diversity, accurate language for human differences, and deep, caring human connections.
- Increasingly recognize unfairness, have language to describe unfairness, and understand that unfairness hurts.
- Demonstrate a sense of empowerment and the skills to act, with others or alone, against prejudice and/or discriminatory actions.

The goals are designed to foster a safe, supportive learning community and to promote healthy social-emotional and cognitive development for all children. As noted in a 2007 report from the National Scientific Council on the Developing Child, "Emotional well-being and social competence provide a strong foundation for emerging cognitive abilities, and together they are the bricks and mortar that comprise the foundation of human development" (NSCDC, p. 8).

At the heart of anti-bias work is a vision of the world in which every child's particular abilities and gifts are able to flourish. In this vision, all children and families have a sense of belonging and experience the affirmation of their identities and cultural ways of being. They all have access to and participate in the education they need to become successful, contributing members of their society. Children and adults know how to respectfully and easily live, learn, and work together in diverse and inclusive environments. All families have the resources they need to fully nurture their children and live in safe, peaceful, healthy, comfortable housing and neighborhoods.

However, too many children do not yet have the necessary opportunities to become all they could be. They live in a world where some people have far more than they need and many do not have enough, and which is not yet a place where all children are able to be safe and secure in their many identities. Consequently, children need tools to navigate the complex issues of identity, diversity, prejudice, and power in their daily lives so that they may learn, thrive, and succeed. Rita Tenorio, an experienced early childhood educator and grade school principal, put it this way:

Racism and other biases are part of our society and part of what children have to learn to deal with, to become savvy about. They have to be ready to take what is their right to have: respect, decent jobs, and a decent education. What we are about in education is preparing children for the future—giving them what they need to be successful. We need to give children a critical perspective

and appropriate tools. Those they will need no matter what they become in life. (Derman-Sparks & Edwards, 2010, p. 3)

Children's Formation of Identity and Attitudes

Anti-bias education is grounded in the body of research about how children construct their identities and attitudes and how social bias and inequity impact that development. (A summary of this research can be found in the 2004 book *Teaching and Learning in a Diverse World*, by Patricia Ramsey.) From infancy on, children distinguish and are curious about all forms of differences among people. In general, by 2 or 3 years old, they verbally demonstrate awareness and wonder about the range of human characteristics, including those related to race, gender, language, and obvious physical disabilities. By 4 or 5 years old, children have already formed the foundation for several of their own social group identities. They have a number of ideas about many aspects of human diversity—ideas that may be unknown or quite surprising to adults. They also are absorbing and acting on misinformation, bias, and unease about various aspects of diversity. Moreover, 4- and 5-year-olds may express discomfort over, or even fear of, specific kinds of differences.

William Cross puts forward the concept of social group identities in addition to personal identity that are central to the anti-bias approach. Social identities, rooted in their families, connect individuals to larger groups beyond their family. They comprise characteristics such as people's racial and ethnic identity, gender, culture, religion, language, economic class, family structure, sexual orientation, and abilities, *as these characteristics are defined by the society in which people live*. Everyone has multiple social group identities, which play a significant role in how individuals are viewed and treated by others. Social group membership also significantly affects access to and treatment from societal institutions, such as education, health, and the legal system.

Kenneth Clark advised us in his pioneering work about young children's racial identity and attitudes that socially prevailing ideas about the various aspects of human diversity affect children's formation of their social group identities and attitudes as much as, or sometimes even more than, direct contact with other individuals. Socially prevailing ideas come to young children from many sources in addition to their families. These include, but are not limited to, the media, advertisements, books, toys (e.g., images on puzzles, card and board games), greeting cards (e.g., Native Americans on Thanksgiving cards), and the visibility or invisibility of diverse people in the community.

The content of socially prevailing ideas about various social group identities reflects the institutional dynamics of all the "isms" (racism, sexism, etc.). As children absorb these ideas, they develop some degree of internalized *oppression* and internalized *privilege*. *Internalized oppression* is about coming to believe hurtful, inaccurate beliefs about oneself and one's groups. These ideas, as Carol Day suggests, can generate anxiety, self-consciousness, shame, disconnection, embarrassment, and fear, resulting in negative perceptions of self as learner, reader, writer, and speaker. *Internalized privilege* is about acquiring a set of beliefs about oneself and one's group that leads people to believe they are entitled to the good things of life regardless of the cost to others. It defines self as "normal" and others as strange, exotic, and "less than." These ideas function as social blinders toward those not in the privileged groups, justifying unfair treatment and access.

While social identities are externally imposed by the beliefs and actions of the society at large, they are also internally constructed by the child's experiences, emotional supports, and cognitive thinking capacities. This is where trusted adults' interventions become central to the child's healthy identity development and his or her ability to navigate in a still inequitable world. How an individual learns to feel personally about his or her social identities may stand in opposition to the societal realities of advantage and disadvantage connected to him or her. For example, social discrimination

and negative messages about being “working class” do not necessarily stop people from being personally proud of their family background. Despite racism, children of color can be supported to feel proud and capable.

Children's Programs

Effective anti-bias education happens when all four anti-bias education goals are part of an early childhood care and education program. *Goal 1* is the starting point for all children. A strong sense of both individual and group identity is the foundation for success in school and in life. *Goal 2* is about teaching children how they are both different from and the same as other children. These are never “either/or” realities because all people are simultaneously the same and different from one another and having language for both aspects is essential to respectful contact. *Goal 3* fosters children's ability to think critically. Children cannot construct a strong self-concept or develop respect for others if they do not know how to identify and resist hurtful, stereotypical, and inaccurate messages or actions directed toward themselves or others. Being able to think critically and skillfully about the world is also a crucial skill for school success and increasingly sophisticated human interactions.

Goal 4 is about helping every child to learn and practice a variety of ways to act when they experience biased behaviors or when they see other children targeted with unfairness. An anti-bias approach considers biased behaviors among children, such as teasing, rejection, and exclusion based on some aspect of a child's identity, as a form of aggressive behavior, however unintended. If a child is the target of prejudice or discrimination, he or she needs tools to resist and to know that he or she has worth. A child speaking up for another child reinforces his or her cognitive capacities for empathy and ability to interact with people of all backgrounds. Helping children learn effective ways to take action broadens their understanding of “unfairness” and “fairness” and building a foundation for becoming a useful citizen of a democratic society.

Educational Principles

The following principles inform the pedagogy that implements the four anti-bias goals.

Children learn prejudice from prejudice—not from learning about human diversity. A common, and incorrect, opinion held by many Americans—especially White Americans—is that noticing and talking with children about diversity and inequity lead to prejudice. Instead, they believe that ignoring and pretending not to see diversity create a nonprejudiced, “color-blind” society. This is simply not true, as the research about the formation of social group identity and attitudes shows. Ignoring this aspect of young children's development does not lead to nonprejudice but rather leaves children alone to figure out and deal with complex issues that deeply affect their social-emotional growth.

The four anti-bias education goals are for everyone and everyone benefits. All children deserve to be visible and equally included in daily classroom activities. Social inequalities and biases undermine healthy development in *all* children in one way or another. However, the specific tasks connected to the goals will vary depending on a child's cultural background, various social identities, and life experiences. For example, children who are members of social and economic groups advantaged by society need to develop positive individual and social group identities but without believing that they are superior to people from other social group backgrounds. Children who are members of social and economic groups disadvantaged by society need to develop positive self and social identities in the face of messages that undermine who they are.

Anti-bias education activities pay attention to the realities of children's lives and their developmental needs. A one-size-fits-all approach does not work. It is necessary for teachers to individualize learning opportunities for children's healthy development of their individual and social identities as well as their attitudes toward and interactions with people different from themselves. Each child, and each group of children, presents different needs and

understandings that require multiple approaches to anti-bias work.

Anti-bias curriculum is a balance of child-initiated and teacher-initiated activities. Children's questions, comments, and behaviors spark teachable moments, as well as long-term projects. They are one vital source of anti-bias curriculum. So, too, are teacher-initiated activities, which enable children to further explore and grow their ideas on a wide range of topics. A balance between child-initiated and teacher-initiated activities throughout the school year is as vital in anti-bias education as in any other part of the early childhood curriculum.

Anti-bias education rests on strong relationships, regular connection, and collaboration between families, staff, and program directors. Families must feel accepted, respected, and part of the program's community to engage actively with anti-bias issues. Involving families and practicing collaboration calls for an inclusive definition of families and multiple, versatile strategies. It also requires that directors and teachers strengthen their knowledge and skills for building partnerships with the families.

Anti-Bias Theory Applied to the Educator's Journey

Good teachers are always in a state of becoming. Becoming an anti-bias educator, however, requires additional levels of personal and professional commitment. As one experienced anti-bias educator and school principal explains,

This work is as much about changing your own perspective as a teacher as it is about the activities you do in the classroom. If you're not willing to make a commitment to the four anti-bias education goals yourself, the rest is not useful. (Derman-Sparks & Edwards, 2010, p. 20)

The goals for the adult journey parallel the goals for children and specify that educators will:

- Increase their awareness and understanding of their own social identity in its many facets

(gender, race, ethnicity, economic class, family structure, sexual orientation, abilities, or disabilities) and their own cultural contexts, both childhood and current.

- Examine what they have learned about differences, value, and what they enjoy or fear across lines of human diversity.
- Identify how they have been advantaged or disadvantaged by the "isms" (e.g., racism, sexism, ethnocentrism, classism, ableism, and heterosexism) and the stereotypes or prejudices they have absorbed about themselves and others.
- Explore their ideas, feelings, and experiences of social justice activism, and open up dialogue with colleagues and families about all these goals.

Learning and practicing ways to implement the four core goals with specific groups of children and families is a developmental process. Most people experience several phases as they deal with the various issues of anti-bias education and are often simultaneously at different places in their growth in relation to the various areas of social identity. For example, an individual may be farther on the anti-bias journey concerning gender and sexism than in comprehension of racism. People embarking on their first steps on the anti-bias journey are faced with looking critically at their own social identities, experiences, and attitudes about themselves and "others" and their understanding of societal inequalities. They grapple with the principle that everyone has a culture and try to identify the characteristics of their own cultures. They move beyond the assumption that there is one right way to care for children.

As individuals take on anti-bias self-reflection work, they may show signs of emotional and intellectual disequilibrium. Feelings such as discomfort, anger, or guilt may arise, as people uncover what they previously did not know or understand. They may doubt all they have learned in their professional training and need to sort out what to keep, modify, or change altogether. In some cases, an individual may respond to his or her disequilibrium by wanting to go back to denial: "I'm all for diversity, but aren't we talking too much about it?" or "Children are still basically children and we are

making too big a fuss about diversity.” They also may respond with relief, even joy, to have words to describe what they experienced and never articulated—and feel profoundly validated to have a context in which to put what they thought was only an individual experience.

Committing to an anti-bias approach in all aspects of their work with children and families is another phase of the journey. Teachers seek greater understanding of their social identities’ influence on their teaching practice. They have more conversations with families and incorporate what they learn into their work with the children. They engage in ongoing thinking with their colleagues and respond to pre-prejudiced behaviors in the children with open conversation and curriculum follow-through. *Pre-prejudice* refers to beginning ideas and feelings in very young children that may develop into real prejudice if not countered by their family and/or teachers.

As the journey continues, anti-bias education becomes the *norm* for teachers. They routinely integrate anti-bias values and concepts into all aspects of their work and are more comfortable collaborating with other teachers and families. They demonstrate more openness and skill dealing with cultural differences and conflicts, whether with children’s family members or another teacher. At this point in their anti-bias journey, teachers may wonder how they could have ever worked with children any other way.

Even when an anti-bias approach becomes the norm for a teacher, there are always new paths to explore and knowledge to acquire. Each new family invites new understandings and approaches. Many anti-bias educators also choose to take action with others beyond their own programs. They might join with families to organize around issues in the early childhood program or in the children’s neighborhood (e.g., convincing local stores not to group toys based on gender stereotypes or getting more playgrounds built with accessible equipment). They might join with colleagues through professional organizations and unions on various early childhood issues (e.g., creating and improving required program and learning standards and assessments) or organize

campaigns to get publishers to put out more books about specific groups of children. They may become involved in state and federal government issues related to early childhood education (e.g., increased funding for programs for low-income families).

Anti-bias education matters for children—it *also* matters for the adults who practice it. As one child care director wrote, “This work helps you to be a whole human being. It is a kind of redemption. It opens your eyes and makes you whole” (Derman-Sparks & Edwards, 2010, p. 20). A worldwide community of educators shares the vision toward which anti-bias education strives. As the work of people such as Babette Brown, Anke Van Keulen, Colette Murray, and Mathias Urban shows, the principles of anti-bias education are adapted to the needs of children and families in their specific context. Such adaptations, in turn, continually reshape and deepen anti-bias practice and theory.

APPROACHES TO EARLY MATHEMATICS INSTRUCTION

How to “best” teach pupils has long been heatedly and unprofitably debated. On one hand, reformers have long been dissatisfied with the limited and even harmful effect of traditional direct instruction. Concerned that traditional direct instruction often fails to promote conceptual understanding, mathematical thinking (e.g., problem-solving and reasoning ability), and a positive disposition toward mathematics (e.g., autonomy, confidence, perseverance), constructivists and other reformers have recommended discovery learning.

Early in the 20th century, the progressive education movement pioneered by John Dewey advocated methods diametrically opposite to traditional methods (e.g., child-centered, instead of teacher-centered, instruction; unguided, rather than guided, instruction). In the 1960s and 1970s, the radical constructivist philosophy of some followers of Jean Piaget reinforced this laissez-faire “free play” or “free school” approach to instruction, which was popular among many early childhood educators and embodied in Summerhill, a school in Great Britain founded by the progressive educator Alexander Sutherland Neill. Louis Alfieri, Patricia Brooks, Naomi Aldrich, and Harriet Tenenbaum (2011) observed that the discovery

approach advocated by constructivists has increasingly replaced direct instruction in recent decades.

On the other hand, proponents of traditional direct instruction have long been skeptical of “reform” efforts. Such proponents considered discovery learning impractical and direct instruction and practice as the most efficient means for achieving skill mastery. Understanding of abstract mathematical concepts was considered beyond the ability of young children, unnecessary for skill learning, or too time consuming and inefficient, especially if discovery learning was involved.

Of particular concern to critics of early reform efforts was that the almost exclusive focus on problem solving and the acquisition of conceptual knowledge effectively shortchanged skill mastery. More recently, Paul A. Kirschner, John Sweller, and Richard E. Clark (2006) argued that discovery/inquiry-based instruction is fundamentally inconsistent with what we know about how human brains learn, because it requires pupils’ working memory to search long-term memory for a strategy or solution-relevant information, and this heavy burden on working memory precludes learning. They concluded that this limitation calls into question the constructivist assumption that children should learn in the same way a discipline such as mathematics has evolved (by constructing knowledge via inquiry and discovery). Richard E. Mayer (2004) observed that, in each decade from 1950 to 1980, research indicated that the popular unguided, problem-based approach—when compared to guided forms of instruction—was unsuccessful; yet constructivists kept adducing discovery approaches under a new name.

Research on Key Issues

The debate about “best practices” has gone on for decades, indeed centuries, because each view contained kernels of truth overlooked by the other camp.

Meaningful Learning That Builds on Child’s Prior (Informal) Knowledge

Reformers make a valid point that meaningful instruction—instruction informed by (existing)

conceptual understanding—is, in the long run, more effective and even more efficient than meaningless direct instruction (efforts to promote factual and procedural knowledge by rote) for two reasons. One is that new knowledge linked to existing understanding is more easily learned and likely to produce retention and thus requires less initial drill and repetitive review. Another reason is that conceptually interconnected knowledge is more likely to transfer—to be applied effectively to learning new content and solving new problems.

Recognition of the importance of promoting meaningful learning has fueled interest in using learning trajectories—efforts to ensure instruction is developmentally appropriate by building step-by-step on what children already know. It has also fueled interest in children’s informal mathematical knowledge (largely verbal knowledge gleaned from everyday experiences)—a key basis for the meaningful learning of formal (school-taught and largely written) mathematics.

Indeed, research indicates that young children are capable of an impressive array of informal knowledge and are far more capable of understanding abstract and important concepts than Piagetian theory suggests. Unfortunately, some children—especially those from low-income families—do not have the opportunity to develop a wealth of informal knowledge, lack the developmental readiness to learn formal mathematics, and fall further and further behind in school.

There is now broad agreement that mathematics instruction should be meaningful—that is, include concepts—and instruction that targets mathematics can profitably begin in the preschool years. For this reason, modern proponents of reform and direct instruction endorse instructional efforts that promote *both* procedural and conceptual knowledge.

Targeted Instruction

Proponents of direct instruction make a valid point that pure child-centered instruction may be inefficient and shortchange the learning of factual and procedural knowledge needed for productive living. Research indicates that unguided discovery

does not benefit learners, whereas guided instruction does. Moreover, explicit instruction of concepts and skills is more likely than implicit instruction to effectively promote learning. Within the field of early childhood education, there is now growing, but by no means unanimous, agreement that free play or exploration is not enough—that even young children can benefit significantly from regular, structured mathematics instruction. This is a view, parenthetically, that would have found favor with founding figures of the field such as Maria Montessori and Friedrich Froebel. Indeed, there is growing recognition that targeted preschool intervention is needed to level the playing field for children living in poverty or otherwise at risk for learning difficulties.

A reflection of this change in view is that Piagetian theory has been replaced as the predominant psychological theory in the field of early childhood education in recent decades by Lev Vygotsky’s (1962) social constructivist theory. Indeed, there is evidence to support more guided forms of early mathematics instruction, even with young children. Consider the following examples:

- Kelly Mix, Julie Moore, and Erin Holcomb (2011) found that 3-year-olds provided toys and a matching container (e.g., Wiffle balls and a muffin tin) outperformed children who were provided with the same toys but without a container on a challenging equivalence (number-matching) task.
- Mix, Catherine Sandhofer, Moore, and Christina Russell (2012) found that only one of four common methods of teaching 3.5-year-olds the cardinality principle (the last number word used in counting a collection indicates the total number of items in the collection) was effective. This was linking counting to a cardinal label, a procedure seldom used by parents.
- Sheri-Lynn Skwarchuk (2009) found that the frequency of complex activities such as comparing quantities or adding and subtracting objects, but not basic activities such as counting or reading and writing numerals, predicted higher mathematical achievement.
- In their review of the research literature, Douglas Frye and colleagues (2013) concluded that

structured pre-K intervention has been successful in promoting numeracy and general mathematics achievement among children at risk for mathematical learning difficulties.

Role of Guided Discovery in Targeted Instruction

The debate about best practices has frequently been heated and unprofitable, because it has often focused on extreme or ill-defined positions. For example, evaluation efforts have often involved examining narrow and extreme forms of discovery learning. Alfieri and colleagues (2011) defined *discovery learning* as not providing learners with the target information . . . but creating the opportunity to “find it independently . . . with only the provided materials” (p. 2). However, the goal of promoting independent insight can be implemented in vastly different ways. Indeed, discovery learning might best be viewed as part of a continuum from completely unguided discovery (in which the child chooses and pursues a task with no guidance from a teacher) to moderately guided discovery (in which the teacher selects a task that is structured to promote students’ independent discovery of a concept or method) to highly guided followed by explicit discovery (in which the teacher selects a task that is structured to promote students’ independent discovery and then summarizes or clarifies their discovery). General conclusions about discovery learning, then, cannot be drawn from research that focuses on a particular form of discovery learning with a particular topic.

The evaluation of discovery learning (or any type of instruction) can be greatly influenced by how well it is implemented. In his 1963 book *Experience and Education*, Dewey distinguished between “educative experiences” (e.g., activities carefully selected to set the stage for learning or to promote particular learning goals) and “miseducative experiences” (activities that are selected, e.g., for their entertainment, rather than pedagogical, value) and concluded progressive education experiments were largely unsuccessful because of

reliance on the latter. Dewey further noted that educative experiences required external factors such as the difficulty of a problem or the content taught to mesh with internal factors such as developmental readiness. Indeed, Jerome Bruner (1961) cautioned that discovery learning can be effective only when pupils are developmentally ready for a constructive activity. Advocates of learning progressions or trajectories emphasize that learning new knowledge meaningfully requires building on developmental prerequisites—foundational concepts and skills.

Proponents of direct instruction now agree that the impact of discovery learning may vary depending on such factors as developmental readiness and the degree of scaffolding. For instance, Kirschner, Sweller, and Clark (2006) noted, although guided instruction is generally more effective than unguided instruction, this advantage recedes “when learners have sufficiently high prior knowledge to provide ‘internal’ guidance” (p. 75). Earlier, David Geary (1996) concluded that radical constructivists failed to distinguish between relatively simple, innately supported knowledge that children can discover and relatively complex knowledge that requires social intervention and, thus, naively proposed discovery learning for learning both. More recently, Geary (2003) allowed that, although unguided discovery learning may be impractical, encouraging students to rediscover concepts and to invent or reinvent procedures *may* prove to be valuable.

In fact, although recent research indicates that unguided discovery learning is typically less effective than guided instruction, it also suggests that guided discovery may have important advantages over direct instruction and is often more effective than other forms of instruction, including direct instruction. One advantage of permitting learners to construct their own knowledge in some way—such as exploring a phenomenon, discovering regularities, and generating their own generalization or solutions—is what Alfieri and colleagues (2011) labeled a “generation effect”: enhanced motivation and understanding and thus learning, retention, and transfer. Research indicates that young children

can use their informal mathematical knowledge to invent their own solution strategies—including those as, or even more, efficient than school-taught strategies and that doing so can provide a foundation for understanding more advanced concepts and procedures. In contrast, direct/explicit instruction on procedures or even procedures plus concepts may undermine a pupil's curiosity or autonomy, forestall a novice's exploration of a domain, inhibit invention of procedures, and produce partial understanding or even confusion—and consequently interfere with transfer. For example, Patrick Shafto (2014) concluded that, with direct instruction (a demonstration by a teacher perceived as knowledgeable), 4- and 5-year-olds assumed nothing more was to be learned, engaged in less subsequent exploration, and learned less than peers who did not see a demonstration from a knowledgeable teacher before exploration.

The “Chinese approach” of combining discovery and direct instruction might achieve the benefits of both approaches and might be more effective than either guided discovery or fully guided instruction alone. For example, Emily Fyfe, Bethany Rittle-Johnson, and Marci DeCaro (2012) found that problem explorations before explicit instruction may better prepare children for explicit instruction and facilitate learning. DeCaro and Rittle-Johnson (2012) found evidence consistent with this hypothesis and concluded that problem exploration facilitated follow-up explicit instruction by helping children “more accurately gauge their competence, attempt a larger variety of strategies, and attend more to problem features” (p. 552).

A series of training experiments by Art Baroody and colleagues (2015, in press) revealed that the degree of guidance needed can vary with difficulty of the content. Whereas minimally guided discovery (unstructured practice, entering a sum on a number list, and feedback about correctness only) was as effective in promoting learning and fluent application of a relatively straightforward and salient add-1 rule as was highly guided discovery, only highly guided discovery was effective in teaching the complex and less salient doubles, use-ten, and subtraction reasoning strategies.

Highly guided instruction may *not* have been needed in the case of the add-1 rule for several reasons. One is that the connection between adding with 1 and number-after relations is relatively obvious. A second is that schoolchildren typically have the prior knowledge needed to notice the connection and implement the add-1 rule. A third is that entering a sum of an add-with-1 combination on a number list may underscore, if only implicitly, the connection between the relatively novel experience of adding 1 and the relatively familiar knowledge of number-after relations.

Research has also revealed several methods that actively involve pupils in learning and that can provide useful scaffolding with a discovery approach. A particularly effective method is to provide children examples *and* nonexamples of a concept so that they can discover for themselves the critical (defining) attributes of the idea. This method can serve to help children reason inductively to construct a wide variety of concepts in early childhood mathematics curricula. For example, young children often initially overgeneralize their use of small-number number words, such as using “three” to refer to any collection with more than two items—that is, synonymously with “many.” Examples and nonexamples of small numbers in everyday situations (e.g., “That’s three cookies, not two cookies”) and playing games (“Can you find examples of three things in the room?”) can help children define precisely the meaning, including the limits, of small-number number words.

Error detection games in which children are asked to help a “confused” adult who sometimes correctly points out a number and sometimes does so incorrectly (e.g., picking up four pencils and saying: “Is this three pencils?”) can serve to model correct and incorrect application of various procedures and concepts and *verbal counting* (“... fourteen, fifteen, sixteen...” = correct example; “... fourteen, fifteen, sixteen...” or “... fourteen, sixteen...” = incorrect examples), *object counting* (counting four items in 1-to-1 fashion = correct example; skipping an item, counting an item and then returning to it later to count it again, or pointing to an item while labeling it with two number

words = incorrect examples), applications of the *cardinality principle* (counting a collection of three correctly and labeling it “three” = correct example; counting a collection of three correctly and labeling it “four” = incorrect example), *numeral reading writing* (writing the numeral 9 correctly and identifying it as “nine” = correct; writing the numeral 6 and identifying it as “six” or writing a “nine” backward or upside down = incorrect example), and the successor principle—each successive number in the counting sequence is exactly one more than its immediate predecessor (“Do I add one to six to make seven?” or “Do I add more than one to six to make eight?” = correct example; “Do I add two to six to make seven?” or “Do I add more than one to six to make seven?” = incorrect examples)—to name a few.

Conclusion

How “best” to teach young children mathematics does not come down to choosing between free play or lecturing children. Providing educative experiences that promote meaningful learning of targeted mathematical knowledge is a complex and challenging task that requires taking into account (assessing) a child’s developmental readiness (place on a learning trajectory) and connecting with the child’s existing knowledge in an engaging and effective manner. Guided discovery learning can play an important, if not a major, role in early childhood mathematics instruction as long as—as Fyfe and colleagues (2012) noted—inquiry or constructive activities are carefully crafted to build on what children know. Well-designed and developmentally appropriate guided approaches might play a useful, if not a leading, role. For example, an educative experience might involve carefully choosing a math game that targets a concept or skill for which a child has already mastered the developmental prerequisites.

standards-setting, curriculum design, and assessment. This entry first provides a brief history and definition of the construct and evidence for specific components. It then summarizes research about the importance of positive approaches to learning in children's development, describes some contemporary and emerging applications, and identifies future issues for approaches-to-learning research, policy, and practice.

History and Definition

The National Education Goals Panel and School Readiness

In the United States, an education summit convened in 1989 by then-President George H. W. Bush identified a set of national education goals. As approved by Congress and signed into law by then-President Bill Clinton in 1994, the first of eight national education goals was “school readiness”: “By the year 2000, all children in America will start school ready to learn.” To flesh out this ambitious target (as yet unmet), a Goal 1 Technical Planning Group on Readiness for School, led by early childhood experts including Barbara Bowman, Sue Bredekamp, Sharon Lynn Kagan, and Lilian Katz, identified five dimensions of early development and learning that research suggested would contribute to later school success. These were (1) physical well-being and motor development, (2) social and emotional development, (3) approaches toward learning, (4) language development, and (5) cognition and general knowledge. The Goal 1 group's definition of the components of school readiness continues to be influential and widely used.

Definitions and Elements of Approaches to Learning

The phrase “approaches toward learning” (often called “approaches to learning”) was coined by the Goal 1 group to emphasize that *how* children learn—the ways that children approach and engage with learning situations—is at least as important as *what* children learn. There is no one agreed-upon definition of approaches to learning: It is a

APPROACHES TO LEARNING

Widely recognized as one of the key dimensions of school readiness, *approaches to learning* is a construct that has been influential in early childhood

sort of umbrella concept that includes a wide array of attitudes, habits, and learning styles. Other phrases that some writers have used as synonyms for approaches to learning are “learning behaviors” and “learning-related skills.”

Head Start’s Child Development and Early Learning Framework includes approaches to learning as one of its six domains. The framework lists three elements of approaches to learning: initiative and curiosity, persistence and attentiveness, and cooperation. Enthusiasm for learning, cognitive flexibility, engagement, focused attention, and motivation to learn are other elements often included under the umbrella of approaches to learning. Children’s executive function skills are considered either as part, or a closely related aspect, of approaches to learning.

To simplify this picture, in *Enthusiastic and Engaged Learners: Approaches to Learning in the Early Childhood Classroom*, Marilou Hyson organized these disparate elements into two main dimensions—an emotional/motivational component (enthusiasm for learning) and an active/behavioral dimension (engagement in learning). In this conceptualization, *enthusiasm* includes the components of interest, pleasure, and motivation to learn. *Engagement* includes the components of attention, persistence, flexibility, and self-regulation.

Evidence for the Importance of Approaches to Learning Components

Although positive approaches to learning are inherently desirable (it is simply good for children to be curious, enjoy learning, and be intrinsically motivated), each component of approaches to learning also contributes to children’s overall development and school success. Examples from just three of these components help make this point.

Motivation to Learn

Children differ in how intrinsically motivated they are. Some children eagerly dive into new learning opportunities without expecting rewards, simply to feel the sense of accomplishment or mastery that comes from hard work. For example,

those children who have higher levels of mastery motivation at age 4 reach higher levels of achievement in language, literacy, and mathematics as they get older—significantly more than one might expect from pretest scores.

Engagement

Researchers assess young children’s engagement primarily by observing them in early childhood settings. Levels of engagement can range from complete disinterest to deep and sustained involvement in a task. Children who are able to become and remain engaged are more competent overall and achieve more in school. Even in kindergarten, children who are more engaged later show greater academic readiness.

Flexibility

When faced with a problem-solving task, such as a challenging puzzle or a new math game, children who try out different ways of dealing with the problem (cognitive flexibility) have higher academic achievement both in kindergarten and first grade. In one study, Head Start children who were more cognitively flexible were later rated by their teachers as being more attentive and persistent, which are aspects of approaches to learning as defined in Head Start’s framework. In turn, these positive approaches to learning predicted children’s academic school readiness.

Influences on Children’s Approaches to Learning

Like other aspects of early development, children’s development of positive, or less positive, approaches to learning is the product of interactions between their inborn characteristics (such as temperament) and influences from their environments. For early childhood educators, the take-home message is that much can be done to create more enthusiastic and engaged young learners. The research evidence is clear: Children are not simply born more, or less, enthusiastic about and engaged in learning. The experiences they have within their family environments, and within the

environments of their early childhood programs, can have a substantial impact.

As with other aspects of development, in the case of approaches to learning, positive relationships with adults, whether parents or teachers, provide a secure foundation for young children to explore, persist, and engage even in frustrating tasks. “Caring communities of learners,” where children are encouraged to help one another and to feel the joy of cooperative effort, help children develop stronger motivation to learn as they get older.

In addition to positive relationships, other aspects of early childhood programs can promote positive approaches to learning. Children who attend high-quality early childhood programs (e.g., programs that help children make choices and become independent but that also provide guidance and scaffolding) are more deeply engaged in learning. The frequent use of small-group learning is another well-tested path toward greater engagement and persistence. Although there is not one best early childhood curriculum, curricula that emphasize the “big ideas”—helping children think about important ideas in developmentally appropriate ways—are likely to produce learners who are more engaged. And motivation is also stimulated when the curriculum frequently integrates learning across subject areas. Additionally, when teachers emphasize what are called “learning goals” (i.e., learning for mastery rather than learning to receive praise or perform well), children have adopted those same goals.

Contemporary Applications of Approaches to Learning in Early Care and Education

The research on these and other components of approaches to learning have stimulated a number of applications in programs, policies, and practices. Again, a few examples illustrate these contemporary trends.

Head Start

As noted earlier, approaches to learning has for some time been one of the key domains in Head Start’s Child Development and Early Learning

Framework. Currently, through Head Start’s online Early Childhood Learning and Knowledge Center (ECLKC), educators are provided with summaries and references to relevant research, detailed descriptions of indicators within each element or component within the approaches to learning domain, and practical strategies for the classroom. Within each domain element, multiple resources are provided, including articles, electronic slide presentations, and “guided practice” resources, intended for teaching teams and for professional development providers.

State Early Learning Guidelines

All 50 states and some territories have standards or “early learning guidelines” (ELGs) describing desired outcomes for preschool-age children. Including the domain of approaches to learning within these guidelines is one way to ensure that the competencies are emphasized in child care and other programs. Many states have followed Head Start’s lead in creating a separate category for approaches to learning. These states often provide programs with resources about approaches to learning, and many offer training specifically on this aspect of the state’s ELGs. However, 16 states do not directly assess this domain in their guidelines. Even when the domain is given its own place in a state’s guidelines, typically there are fewer indicators than for other domains, suggesting that approaches to learning may be considered a less important aspect of school readiness.

Curriculum

As noted earlier in this entry, there is no one curriculum that is best for young children, either in general or in promoting positive approaches to learning. Aligning with Head Start’s domains and with state ELGs, a number of often-used curricula have explicitly included approaches to learning as an area of emphasis. Other curricula reflect this emphasis in other ways, such as by emphasizing child-initiated projects or activities that encourage flexible problem solving, persistence, and intrinsic motivation, rather than relying on external rewards.

One curriculum is notable for its focused attention on developing children's approaches to learning or learning behaviors. Implemented in a number of Head Start programs, the EPIC curriculum (Evidence-Based Program for the Integration of Curricula) integrates intentional teaching of approaches-to-learning skills into literacy and mathematics activities. For example, children's books are used both to develop foundational language and literacy competence and to emphasize themes such as attention control and frustration tolerance. When evaluated in a randomized comparison with another curriculum, both curricula benefited literacy skills, but EPIC showed more positive effects on approaches to learning as well as on mathematics and listening comprehension.

Assessment

If early childhood programs intend to strengthen children's approaches to learning, effective assessment is essential—as long as that assessment is consistent with generally accepted best practices in the design, implementation, and uses of early childhood assessment. A number of widely used assessment systems already include items that tap into children's development of persistence, curiosity, problem-solving behaviors, and other approaches-to-learning-related competencies. There are also measures specifically intended to help classroom teachers assess the amount and level of children's engagement (the Scale for Teachers' Assessment of Routines Engagement [STARE] is an example) and other learning behaviors (the Learning-to-Learn Scales). Still other assessments are used by researchers to study specific aspects of approaches to learning such as self-regulation and cognitive flexibility.

New Directions in Approaches to Learning for Younger and Older Children

Looking toward the future, there are signs that the emphasis on fostering positive approaches to learning, now mostly confined to the preschool years, may be extending both upward and downward.

K–12 Standards and the Common Core

The phrase “approaches to learning” is not one that has been used in K–12 education. However, much of the research on specific components has been conducted with older children; for example, numerous studies have examined elementary and secondary school-age children's motivation to learn and engagement in learning activities, with similar results as studies with preschoolers. Encouragingly, recent surveys of state standards suggest that more states are including social and emotional learning within their expectations for children beyond preschool age, although the domain of approaches to learning is rarely represented as such.

In all, 46 states adopted the standards (including Minnesota, which adopted the English language arts, but not the math, standards).

The adoption of the K–12 Common Core State Standards (CCSS) by, as of early 2015, 43 states and the District of Columbia might at first suggest a neglect of approaches to learning, as the only domains specifically included are language/literacy and mathematics, with science standards recently developed by a separate body. However, a number of the standards themselves, including standards specific to kindergarten and the early grades, seem to require children to use approaches to learning such as persistence and flexibility. (For example, one of the “mathematical practices” for kindergarten is “Make sense of problems and persevere in solving them” [NGA & CCSSO, 2010b, p. 10]; in literacy, a kindergarten expectation is “Ask and answer questions in order to seek help, get information, or clarify something that is not understood” [NGA & CCSSO, 2010a, p. 23].) Furthermore, both in language/literacy and mathematics, the CCSS emphasis on greater depth and focus in students' learning seems to call for more intentional emphasis on strengthening what early childhood educators would think of as approaches to learning. Perhaps in response to these new developments, New Jersey is beginning to develop explicit approaches to learning standards for Grades K–3.

Infant–Toddler Programs

Turning to the other end of the early childhood age range, educators and developmental psychologists increasingly recognize that the foundations of positive approaches to learning are encouraged and established in the first three years of life. Early Head Start has recently addressed this issue, identifying attention, curiosity, information gathering, memory, persistence, and problem solving as critical aspects of approaches to learning for babies and toddlers. A three-part “News You Can Use” online publication offers research evidence and extensive resources for both center- and home-based Early Head Start settings, making close connections with recent research on self-regulation and tying these competencies closely to later school readiness and school success.

Similarly, as states are extending their ELGs downward to infants and toddlers (as of January 2014, according to the Center on Enhancing Early Learning Outcomes, 47 states and the District of Columbia included this age group in their documents), some are beginning to consider how to represent the approaches to learning domain within standards for these very young children, emphasizing its importance but also creating expectations and strategies that are developmentally appropriate. For example, Oklahoma’s infant/toddler guidelines include this standard: “The child will demonstrate interest in learning through persistence and varying degrees of initiative, curiosity, sensory exploration and problem solving” (Oklahoma Department of Human Services, p. 7).

Conclusion

With renewed research attention to what are sometimes—and, in the view of many, erroneously—called the noncognitive aspects of school readiness and early learning, approaches to learning is a domain that is being given increased emphasis in the United States and beyond. In its recent conceptual framework on school readiness, the United Nations Children’s Fund (UNICEF) includes approaches to learning as one of the key dimensions, thereby

encouraging inclusion of this aspect of readiness in early childhood initiatives within both developed and developing countries. In countries where the concept of “readiness” has narrowly targeted literacy and mathematics skills, an approaches-to-learning emphasis can contribute to a more holistic perspective on young children’s needs, including children whose development is in jeopardy because of poverty, war, and other risk factors.

To make an even greater impact, additional research is needed on specific aspects of approaches to learning. For example, more research is needed with culturally and linguistically diverse children, families, and educators, to identify common themes and specific needs. More studies are also needed with younger children, as some of the strongest evidence for motivation and engagement has been limited to research on elementary-age children. Also needed are comprehensive syntheses of research on this domain of readiness, integrating evidence from studies from diverse disciplines, often using diverse terminologies and methods. As a next step, this evidence needs to be put into formats that make it meaningful and accessible to practitioners and policy makers, using evidence-based strategies from the growing field of implementation science. As part of a broader effort to improve professional development, both pre- and in-service teacher education can help early childhood educators implement practices that strengthen and validly assess children’s approaches to learning. This professional development can draw upon, and contribute to, a growing body of knowledge about the complex and essential domain of young children’s approaches to learning.

ART

Art provides the focus of many activities in an early childhood classroom. Through drawing, painting, modeling, cutting, and assembling, children explore materials and tools while learning to express ideas and emotions. By observing children engaged in art activities and the products they create, adults learn about children's feelings and understandings, their capabilities, and their potential. This entry first discusses how art supports the development of the whole child as well as children's artistic development. It then discusses the components of an early childhood art program, the physical components of the art center, how art relates to subjects across the curriculum, and the assessment of children's artwork.

Art and the Whole Child

Art has traditionally been an important component in early childhood classrooms because it supports the development of the whole child. Young children involved in both making their own art and enjoying the art of others are developing socioemotional, cognitive, and motor abilities.

Art and Socioemotional Development. Deciding what art materials to use and what to create may be the first opportunity many children have to make independent decisions and choices. Making art also builds children's self-esteem by giving them positive avenues for expressing thoughts and emotions. Talking to other children and to adults about their artwork provides practice for children in giving and receiving critiques and compliments. Small group art activities help children practice important social skills like negotiating for and sharing materials and taking turns.

Art and Cognitive Development. Art provides young children with their first experiences in making symbols as they work to represent people and objects. This early use of symbols is very important because it is the foundation for children's later use of words and letters as symbols in formal

writing. Making art also introduces young children to the task of self-evaluation as they review their efforts and identify changes to make in future drawings or paintings.

Art and Motor Development. Young children develop control of large and small muscle groups during art-making activities. Large arm movements used in drawing or painting at an easel or on large paper on the floor build strength and coordination. Smaller movements of wrists, hands, and fingers while cutting with scissors, kneading clay, and drawing or painting on smaller surfaces build fine motor dexterity and precision. Children gain confidence in using tools with repeated practice.

Eye-hand coordination is important for many activities, including formal writing. As children determine how to fit parts to make a whole, what details to include in their art, and where component objects should be placed, they learn to coordinate what they see with the movements of their fingers and hands.

Children's Artistic Development

The earliest experiences children have with art materials are much more closely related to science than to the fine arts. When moving a crayon or a marker across a surface to make marks, children focus primarily on the sensory experience rather than on representing ideas or expressing emotions. They are preoccupied with the textures of the surface, the feel of the tool, and the shapes and colors that appear. Around the ages of 3 to 4 years, children may begin to perceive similarities between marks they have made and real objects. It is at this point that children begin to realize that their art can symbolize people, events, objects, and ideas.

The *mandala*, variations of a circle intersected by lines, is a common element in the art of children of all cultures. Likewise, the *tadpole person*, a circle or oval signifying a head with extended lines to represent arms and legs, is also commonly found in the artwork of most children during their preschool years. Around the age of 5, children begin to draw individual symbols to represent people

and objects. A symbol commonly used for a house, for example, is a square with a triangle on top. Children seem to employ this symbol regardless of the appearance of their own houses or those in their immediate environments. During the early elementary years, children continue to create symbolized drawings. Also during this time, individual children develop a tendency to repeat a specific theme in their drawings. A house with a chimney and a tree beside it and the sun and clouds overhead, a race car with smoke coming out the tailpipe, or a unicorn under a rainbow may be drawn over and over again without deviation as the child works to perfect the symbols in his or her art.

During the middle and later elementary years, children attempt to achieve photographic realism in their art. This fixation on realism can leave children so frustrated that they convince themselves they have no artistic abilities and refuse to participate in art activities.

Just as children's art production follows a predictable pattern, so also does their aesthetic appreciation of art. Preschoolers base their opinions of art on those of their parents or teachers, believing that these authority figures determine what is "good" art and what is "bad" art. Primary grade children form opinions around the subject matter of the art; if the art depicts a subject they view as positive, such as puppies or sunshine, then the art is good. If, however, the subject is not liked by the individual child, as may be the case of art depicting a storm or a frightening animal, the art is viewed negatively. Children in the middle elementary grades focus on realism. The more realistic the art, the better it is.

The Early Childhood Art Program

The overall goals of an art program in an early childhood classroom are that children will be able to identify and understand visual relationships, that children will participate in making art in many forms, that they will learn about art from their own and other cultures, and that they will talk about their own art and the art of others. In support of these goals, there are four components to an early childhood art program: sensory experiences, aesthetic experiences, making art, and appreciating art.

Sensory Experiences. Children do not create art in a vacuum. Their art stems from something they have personally experienced: an event, an emotion, an object, or a person. Children's daily experiences provide them with a depository of things to include in their art. Hands-on experiences through field trips, classroom visitors, and real, authentic objects that children can explore and manipulate are essential in the classroom. They will help children form concepts and will serve as springboards for creating art, writing activities, and oral language.

Aesthetic Experiences. Aesthetics is the study of beauty in color, form, and design. Like adults, children have a need to make sense of and appreciate themselves and their environment. Children pursue beauty with their senses and their bodies. They visually explore art with their eyes and listen for sounds and music with their ears. Three-dimensional artwork is explored through the sense of touch, and children use their bodies to respond to music through movement and dance. Young children learn to appreciate beauty through these rich aesthetic experiences.

Making Art. Experimentation, exploration, discovery, and invention are important elements in art-making activities for children. Although adults have the responsibility for teaching children to use art tools and materials correctly and safely, they should not give explicit instruction about the subjects or ideas children will portray in their artwork. The decision making in which children engage when choosing their own subject, perspective, and style is an important cognitive ability, and making art provides an ideal setting in which children can practice it. Generally, loosely structured planned activities will encourage children's creative expression. The younger the children are, the more these activities should focus on process rather than product.

Appreciating Art. In every place and every time, people have created art. Viewing and discussing works of art in different media and from different cultures and historical eras is essential if children are to develop an understanding of what art is and what artists do. Children come to understand the concepts of art and artist as they talk about their

own art. Adults display the art of others and discuss with children the artist who created the work, the processes used by the artist, and the story the art tells. The focus should be on exposing children to the rich artistic heritage that is theirs, rather than on teaching art history.

The Art Center

The classroom art center is where most children will go to engage in art. In the early childhood classroom, the art center is a workshop where children can experiment and explore without being overly worried about noise and mess. Ideally, the art center is well lit and located on tile floor near a classroom sink. The art center is equipped for a specific age group. Chairs, easels, tables, and shelves are at a height that children can access independently. Shelves and cabinets in the center provide storage for art materials and tools. Bulletin boards and counter tops allow for the display of children's two- and three-dimensional artwork. Children's activities in the art center are suggested by the materials that are provided. Although the number of choices is limited to a few at a time, children are encouraged to use and even mix media and tools. The materials available to children in the art center are safe and open-ended. Although exploration and experimentation are encouraged, the art center has rules and limits for children's behavior and interactions. The number of children working in the center at one time is determined by the available space, but social interaction is an important component of center activity.

The media provided in the art center is varied and all open-ended. Children may draw with crayons, chalk, or markers. They may paint with finger paints, tempera paints, or water colors, working at easels or on tabletops or floors. Scissors and glue sticks may be used for cutting and assembling paper, fabric, or other materials. Clay and other types of dough materials are available for modeling and sculpting. Repeated experiences lead to eventual mastery of the media and allow the children to focus on expression rather than developing skills. However, too much repetition leads to boredom. For this reason, materials are regularly rotated.

Art Across the Curriculum

Although art in itself constitutes a meaningful component of the early childhood curriculum, it also provides reinforcement and extension in other curriculum areas. Integrating art gives children opportunities to think about what they are learning as they create images and artifacts that reflect their experiences. Mathematics and art are natural partners because children quantify as they create, rolling eight legs out of clay for the spiders they are sculpting, and making sure that all five members are represented in the family portrait they are painting. Similarly, shape and size are always considerations as children draw, paint, or sculpt a large oval for a dog's body and a smaller one for his head, or divide a large rectangle into smaller rectangles to represent window panes. Art making also provides numerous opportunities for children to observe and experience the properties of matter so important in science: the thickness of paint at the easel, the intensity of color in the pastels, the resistance in trying to cut cardboard with scissors, the speed of paint drying in the sun. As with the language arts, art provides children opportunities to represent their ideas nonverbally. Children often read artwork, especially their own artwork, in much the same ways that adults read text—drawing a series of ideas or events from the images presented. In the social studies curriculum, drawings and paintings are the only visual representations we have to share with children of many historical events. Art has been a part of every culture throughout history. Appreciating and making art help children to connect with others, now and in times past.

Assessing Children's Artwork

Although art in the early childhood classroom is process-oriented and child-centered, it is still important that teachers carefully observe children as they engage in art. Over time, such observations will give teachers information about children's learning and development. Does an individual child approach new tools and media in the art center with confidence? Or is he reluctant to try

something new? How does the child respond to a compliment or criticism of her artwork? Does the child share the markers and crayons on the art table? Is the child willing to display his artwork, or does he want to take it home? Answers to questions like these can help adults to understand children's socioemotional development while observations of children's use of art tools provide documentation on children's gross and fine motor skills. Talking to children about their artwork provides information about children's symbolic thinking and other aspects of cognitive development.

Art portfolios provide a means of documenting children's artistic progress. Art portfolios should contain representative samples of children's artwork over time and records of children's explanations or descriptions of their efforts. They may contain photographs of art displays in the classroom and video recordings of children at work. Entries should be added regularly and accompanied by information provided by the child. Teachers may ask children to talk about their favorite art media and tools, the processes used to create a particular piece, or why they want to include this artwork in their portfolios. Teachers should review children's art portfolios frequently—not with the goal of comparing children and their work, but to identify and document each child's individual learning and development over time.

ARTS INTEGRATION

Arts integration is an approach to curriculum that connects learning in the arts and learning in the other subject areas. At its most basic level, arts integration is used as a pedagogical tool, such as examining paintings to study geometric shapes or using drama to improve reading comprehension. At its highest level, arts integration teaches and assesses the content of both the art form and the other subject areas. It is grounded in the belief that children are active and reflective learners. This entry addresses theory and research that support arts integration, discusses its importance, and notes applications.

Overview

The Arts Education Partnership (AEP) describes the disciplines of dance, drama, music, and visual art as subject areas with unique concepts and skills. All of the arts, known as art forms, connect with learning in other subject areas. The arts have always been central to good early childhood programs. When children sketch parts of a flower or sing songs about the seasons, they are using the arts to enhance learning in another subject area. These connected experiences complement, but do not replace, other subject area instruction.

Arts integration is a systematic, intentional approach to curriculum that uses three primary attributes—form, content, and process.

Form is a way of thinking and expressing. The form, in which a child demonstrates a concept or event through drama, art, movement, or music, is tied closely to content. Engaging with different art

forms and media offers children opportunities to think, reflect, and express themselves using materials chosen for a specific purpose. They also show what they may or may not be able to say through spoken language.

Content includes the knowledge, skills, and concepts in both the arts and other subject areas. Multisensory experiences with content give children many ways to think about it and show what they have learned. Just as developmental domains are interconnected, so, too, are content areas. For example, children learn scientific and engineering concepts when they build with blocks and plan and design structures; they learn concepts in math and art by using a similar vocabulary such as line shape, space, and color; they build basic geography skills by creating murals and maps in social studies; and they use methods of a historian to create dramatic enactments of events.

Process includes the artistic skills of creating, presenting, performing, responding, connecting, and reflecting all that children need to be able to use and do. Children use process skills when analyzing and producing art and gain important knowledge in learning to perceive and think. Engaging in arts integration uses visual, relational, and expressive concepts.

Theory and Research

The work of Elliot Eisner, John Dewey, and Howard Gardner is particularly relevant to arts integration. Eisner asserts that arts integration is a powerful learning tool that provides experiences that enrich children's lives, increase their capacity for thinking, and expand their creative ability. For Eisner, the arts make distinct and important cognitive contributions to a child's development. Dewey's theory of experiential learning suggests that the arts are a way to express meaning and create authentic learning activities while Gardner's theory of multiple intelligences (MI) asserts that humans use many symbol systems to communicate and the arts are one way humans make meaning and communicate different messages.

A body of research also supports arts integration in the following areas:

Twenty-first-century skills, the skills of critical thinking, problem solving, communication, collaboration, and creating that help prepare children for success in today's global world.

Assessment, the focus on what children know, understand, and can do. Asking questions and finding out the answers, making models, and self-assessment are integral to arts integration and demonstrate conceptual knowledge that standardized tests do not assess.

Developmentally appropriate practice, using knowledge of children's development to plan curriculum by taking into account children's needs, interests, and ways of learning so every child can learn.

Neuroscience research on how people learn that informs connections between the arts and other areas of learning.

Standards, as with the voluntary 2014 National Core Arts Standards, which provide expectations of what every PreK–12 child should know and be able to do in the arts by focusing on the artistic process skills of creating, presenting, performing, responding, and connecting. The National Core Arts Standards align with the Common Core State Standards for English language arts and math.

Visual literacy, the ability to understand, use, interpret, and create images to communicate in today's increasingly visual world.

Importance

The arts are essential disciplines of the core curriculum. They strengthen learning in all domains, have the ability to transform the learning environment, and positively impact student learning. They also provide opportunities for children to make good judgments about materials, ideas, and relationships and discover that problems can have more than one solution, instead of merely providing singularly correct answers to questions. Using their minds and

bodies in, with, and through different art forms, children learn to persist with motivating materials, projects, or ideas and increase their memory, attention, spatial, and empathy skills.

Arts integration is a powerful approach to curriculum that makes the arts evident throughout the day. It provides a way to organize experiences around expected outcomes, to learn how and when to teach specific content, and to determine how best to assess children's learning. It gives children access to unique ways of knowing and displaying their knowledge, transforms how others perceive them, reveals abilities in learners previously unrecognized by others, builds community by providing opportunities for collaboration, and increases students' self-awareness and personal skills required for success such as planning, persistence, perseverance, and time management. Arts integration is a universal language that helps children learn through, in, and with the arts by keeping their bodies and minds engaged in learning.

Applications

Arts integration is a powerful learning approach for all children. Each art form is part of every world culture and communicates the people's values, traditions, and principles. In the early childhood classroom, arts integration motivates students to apply their knowledge, to work cooperatively, and to make connections across content areas. Teaching effectively to meet the needs of children of all abilities requires knowledgeable adults. Using the arts to tap into children's senses and learning modalities engages children at their own learning level. The arts hook children's learning through observing, listening, and moving.

For children with specific exceptionalities, the arts can open doors. All art forms can help children make sense of their world. Like reading and mathematics, all art making involves a linear process and completing a work of art requires cognitive organization. Arts integration gives each child a chance to work concretely to create a meaningful product and to strengthen skills during the process.

ASSESSING CHILDREN FOR DISABILITIES

Assessment is the process of collecting information about what young children know and can do for the purposes of decision making. When a parent, medical professional, or teacher suspects that a young child is developing slowly or in ways that would be considered atypical, an assessment is conducted to determine whether a disability is present. This entry discusses considerations related to the assessment of young children to determine the presence of one or more disabilities. These same assessments also often determine eligibility for services, such as early intervention services for children from birth to 3 years old and early childhood

special education services for 3- through 5-year-olds provided under the Individuals with Disabilities Education Act (IDEA).

Defining Disability

Assessing for disability requires having criteria for what constitutes a disability. The concept of disability continues to evolve with the most recent shift being from a medical model to a model that recognizes the social and environmental contexts of disability. Traditional taxonomies that have been used to classify disability, such as the World Health Organization's (WHO's) *International Classification of Diseases* (ICD-10) or the American Psychiatric Association's *Diagnostic and Statistical Manual of Mental Disorders* (DSM-5), focus on medical conditions and view disability as a characteristic of the child.

The more recent conception of disability includes an emphasis on function rather than impairment and emphasizes that disability involves the interaction of the person with the environment. This new framework sees disability in young children as a developing process with the potential for development to be positively or negatively impacted by features of the child's environment, including whether the child is receiving specialized services. The WHO's *International Classification of Functioning, Disability and Health: Children and Youth Version* (ICF-CY), which reflects this new framework, is a taxonomy for describing health and health-related states and sees health conditions interacting with personal and environmental factors. These factors affect functioning of the body, the person, and how the person functions in social situations. The taxonomy includes impairments, activity limitations, or participation restrictions.

For young children, an especially salient feature of disability is the gap between what the child can do and what the child is expected to do given his or her age. This gap can limit the child's ability to be able to fully participate in various activities of childhood. The participation dimension is important for capturing the extent to which the child is not able to participate with peers and family members in day-to-day activities. This approach to

defining disability differs substantially from a more medically based approach whereby the child is given a diagnosis as the primary descriptor. The ICF-CY is a major advancement in the assessment of disabilities because it provides a common language for describing childhood disability across multiple fields such as medicine, social services, and education, which thus far have approached disability from different perspectives resulting in differing eligibility criteria and challenges to coordination of services across multiple systems.

Screening for Disability

Estimates of the prevalence of disabilities in young children vary, in part because of the difficulties in defining disability. The Census Bureau in 2005 reported that 1.9% of the population of children younger than 3 years of age had a disability, as did 3.8% of the children ages 3 to 5 years. States reported to the U.S. Department of Education that 334,000 children, or 2.8% of the population birth to 3 years of age, had received early intervention services in 2012. For 3- to 5-year-olds receiving early childhood special education, the comparable figures were 750,000 children, or 6.0% of the population.

Assessment can take different forms and serve different purposes depending on the nature of the child's established or suspected disability. Of the preschoolers who received early childhood special education services in 2012, 45% were eligible because of a speech or language delay and another 37% because of developmental delays. Some disabilities, such as impairments of body structure or some health or genetic conditions, are relatively easy to identify. Children with conditions such as Down syndrome or birth defects will be diagnosed as infants by medical personnel. These types of disabilities are relatively rare. Other disabilities—in fact, most disabilities—in young children cannot be detected, or even suspected, by just looking at the child. Over 80% of the children who received early childhood special education services would appear typically developing to a casual observer. All of these children had disabilities that required an assessment to verify the presence of a developmental problem.

Identification of these disabilities involves careful observation and more detailed assessment processes of the child's functioning in multiple domains, such as communication and self-help skills. Ideally, health care providers and staff in programs in the community for young children and their families, such as child care centers and preschools, have implemented developmental screening. The American Academy of Pediatrics recommends that screening tests be administered at the child's 9-, 18-, and 30-month visits to the pediatrician. Developmental and behavioral screening involves the administration of one or more screening tools that are quick assessments in one or more areas of development to determine if the child should be referred for a more in-depth assessment.

Screening also should be conducted regularly in vision and hearing because disabilities in these areas in young children are often easy to miss. Children who do not pass a screening in one or more areas should be referred for further assessment. Without systematic developmental screening in the child's community, someone familiar with the child will need to notice something unusual about the child's development and encourage parents to pursue additional assessment. Developmental screening is strongly advocated because mild delays in areas such as fine motor development or communication skills can be easy to miss unless a significant adult in the child's life is very familiar with what typical development looks like. Developmental screening also is the key to getting young children the help they need as early in life as possible to prevent the occurrence of any additional developmental problems.

Comprehensive Assessment to Identify Delays and Disabilities

Children with suspected vision or hearing problems are referred to the appropriate professional for an examination. Children with suspected delays in one or more areas of development will receive an assessment in that area at a minimum. Ideally, the assessment will include the collection of information

about what the child can and cannot do in multiple areas of development even if a delay is suspected in only one area. Multiple areas would include communication (articulation, expressive and receptive language), motor (fine and gross motor skills), adaptive or self-help skills such as feeding and dressing, and social-emotional development. All areas of development should be assessed because delays in one area of development frequently co-occur with delays in other areas.

This kind of assessment can be administered by a health care practitioner, a psychologist, an early childhood special education teacher, a speech language pathologist, a physical therapist, or other professional skilled in working with young children. Often, professionals from different disciplines will work as a team to evaluate different areas of development and then combine their findings into one comprehensive report. There are various tools that a practitioner can use for this purpose, but a common feature of all these tools is that they produce a score that provides a comparison of the child's developmental level in a domain to how the general population of children the same age perform in this area. For the purposes of identifying a delay, the results of an assessment can be expressed as a standard deviation or as an age equivalent score. An example of an assessment finding would be that the child scored 2 standard deviations below the norm in gross motor skills. A standard deviation is a statistic that conveys distance from an average—in this instance, the average performance of other children the same age. Expressed as an age equivalent, an example of an assessment result would be that the child is 39 months old with the receptive language skills of an 18-month-old.

The assessment of a developmental delay should never be based solely on scores from a single assessment because the child's performance on any given day or with a particular assessor might not be typical of what the child knows and can do. The child's family and other adults who regularly interact with the child, such as a child care provider, are important sources of information on what the child does in everyday routines and activities; information from these sources should be incorporated into the

assessment process and the assessment findings. The assessor needs to get a complete picture of what the child is like in settings familiar to the child to ensure an accurate representation of the child's competencies.

Any formal tool(s) used in the assessment process should be appropriate to the child's unique characteristics, including the child's ability to communicate with the examiner, respond to requests, manipulate objects, or complete other performance demands. Needless to say, the assessment should be administered in the child's home language. The Division for Early Childhood of the Council for Exceptional Children has developed a set of recommended practices for professionals who provide services to young children with disabilities and their families. One set of the recommended practices addresses the assessment of young children with disabilities, and many of the assessment practices apply to assessments administered for the purposes of establishing whether the child is experiencing a delay in development or developing atypically.

All children in the United States from birth to age 5 with delays and disabilities are entitled to special services under IDEA. To be eligible for early intervention services, the child must be younger than 3 years of age and have a delay in development, a diagnosed physical or mental condition that has a high probability of resulting in developmental delay (e.g., blindness), or, if the state opts to serve children who are at risk, a risk condition as defined by the state that may result in delayed development. Children with diagnosed conditions or with a risk condition do not need to be assessed to establish eligibility for services but should be assessed nevertheless so that the professionals who will be working with the child have a good understanding of what the child knows and can do.

Children with suspected delays will receive a comprehensive multi-domain assessment to determine the child's eligibility for services. The criteria that define a delay are established by each state and vary somewhat across the United States. Contrasting examples of state eligibility criteria are Florida, where children must have a delay of 1.5 standard deviations in two or more developmental

areas or 2 standard deviations in one area, and Maryland, which requires a 25% delay in one or more developmental areas or that the child manifest atypical development in one or more developmental areas.

IDEA services for children 3 to 5 years of age have a different set of criteria for program eligibility. To be eligible for early childhood special education, a child must have a disability in 1 of 13 categories: intellectual disability, hearing impairment, speech or language impairment, visual impairment, emotional disturbance, orthopedic impairment, other health impairment, specific learning disability, deaf-blindness, multiple disabilities, autism, traumatic brain injury, or developmental delay. Only a few of these categories require a developmental assessment as the basis for determining eligibility. The use of developmental delay is similar for children younger and older than age 3, but the criteria may not be the same, even within the same state. The different eligibility criteria for early intervention and early childhood special education provide a good example of the need for a more unified and functional approach to defining disability, such as the framework embodied in the WHO's ICF-CY.

ASSESSMENT, LIMITATIONS OF

Assessment is broadly defined as a systematic process for gathering information to make an informed decision. An integral part of early childhood programs, it uses observation, interviews, tests, and other techniques to collect information about children, families, classrooms, and programs. Assessment includes both formal approaches such as standardized tests and more informal processes such as portfolios and conversations with other caregivers. Both approaches are valuable as decision-making tools, but like any tool, they have strengths and limitations. Limitations of assessments are features that reduce proper application and interpretability—in essence, features that impair the ability to use an assessment tool to produce useful, meaningful, and accurate information. Factors to consider when judging the appropriate use of an assessment include the purpose or goal of assessment, the design of the approach, technical and psychometric characteristics, the appropriateness of a given tool

for a particular population, and the conditions of administration.

Because the goal of assessment is to provide information beyond what one could gather without systematic collection, the need to understand how the information can and cannot be accurately interpreted is paramount to the appropriate use of assessments. The focus of this entry is on limitations of standardized approaches because the early childhood field has demonstrated leadership in clarifying appropriate and inappropriate uses of standardized assessments with young children and in early childhood programs through publication of such landmark documents as the National Association for the Education of Young Children's 2003 position statement on curriculum, assessment, and program evaluation.

Purposes of Assessment

Assessments are developed for specific purposes, and these purposes drive their design and appropriate use. Purposes of standardized testing include screening, diagnosis, program evaluation, and accountability. Relative to use, using an assessment designed for one purpose for another carries major risks to accurate interpretation.

Screening

Screening is a brief procedure or test designed to identify children who may need further assessment to identify a developmental delay or health condition. Screening assessments provide basic information about a child's development. A screening may be a first step to know whether a child needs an intervention, but it must be followed up with additional assessment, as it lacks the psychometric rigor to inform diagnoses. An example of a screener is the Ages and Stages Questionnaire (ASQ).

Diagnosis

Some tests are designed to make decisions that will significantly impact the child's life. Decisions such as the diagnosis of a developmental delay will impact a child's life by qualifying the child and the

child's family to receive intervention services or other resources. Because of the stakes or consequences involved in this decision, a test designed for this purpose should have been developed through rigorous testing for reliability and validity. Specifically, recommendations for the reliability of a test used to make decisions about diagnosis or placement should reach levels of .9 on internal consistency reliability. An example of an assessment that meets this level of rigor is the Battelle Developmental Inventory (BDI), which provides a comprehensive assessment of five major developmental domains designed for children birth through age 8.

Program Evaluation

The use of assessment for program evaluation is a third distinct purpose. Relative to program evaluation, concerns about assessment burden on children, potential program cost, and the body of research linking classroom quality to child outcomes has led to a focus on measuring the inputs to healthy child development—that is, the early care environment. Thus, for program evaluation, the early childhood field has developed, and continues to develop, assessments that evaluate the quality of early childhood classrooms. For example, classroom observational tools such as the Early Childhood Environment Rating Scales–Revised (ECERS-R) are widely used to assess the global quality of preschool classrooms as one component to inform program improvement efforts. Data from program evaluations generally serves two purposes—to inform the program and guide improvements or to inform stakeholders who will make decisions about the program's future.

Accountability

In some cases, evaluations hold significant consequences for a program. In essence, this is the definition of accountability assessment—assessments for children or programs that have high-stakes consequences associated with the results. Such is the case with the use of the Classroom Assessment Scoring System (CLASS) Pre-K in Head Start classrooms since the Improving Head

Start for School Readiness Act of 2007 mandated the monitoring reviews of Head Start agencies include a valid and reliable research-based instrument to assess classroom quality and teacher–child interactions. While the 2014 revision of the *Standards for Educational and Psychological Testing* recommends a body of evidence to establish the precision of an instrument, historical recommendations by psychometric experts have provided guidelines. For example, Jum C. Nunnally recommended that measures used for important decisions in applied settings have a coefficient alpha of .9 or higher. The CLASS PreK met this reliability criterion, with an alpha of .9 in one study of 82 classrooms, but in four other studies, the alphas ranged between .79 and .89. This high-stakes use of the CLASS is the first national use evident in the early childhood field. The benefits and unintended consequences of this use remain to be seen.

Measurement Design

Another potential limitation is related to how tests are designed. At an early stage in development, designers develop a test blueprint to focus the measure. As test developers purposely focus on certain areas of child development or early childhood practice, there are always some concepts, skills, or pieces of information that must be left out of the blueprint. Thus, by design, a test only samples the universe of potential items. After creating a blueprint that focuses the measure on specific skills, concepts, or practices, these focus points are further limited by the need to operationalize, or measure with observable or reportable behaviors, the selected skills or concepts. Thus, the items used in a final version of an assessment represent a small sample of many possible items that would be important or meaningful to know about as a parent, teacher, or researcher.

Once the construct is developed through the selection of sample items that are observable or reportable, the items must be used with a diverse group of children. The sample of children used to

develop the measure should be representative of the population with which the measure is intended to be used. For example, if an assessment was developed to measure language development, a normative sample will be developed to compare one child's assessment to other children. If the normative sample was developed with monolingual English speakers, the data will have limited usefulness for understanding the development of language for bilingual English-Spanish speakers.

A final limiting psychometric property that is impacted by design is measurement error. All measures have some level of error. Standard error of measurement (SEM) is a characteristic of the test and is related to the reliability of a measure. SEM can be used to construct a range around a score that explains how much variation exists due to error. Measurement developers may set acceptable levels of measurement error based on the expected use of the instrument. A developer would then continue working on perfecting a set of items that would produce these acceptable levels of error, while protecting overall reliability and validity.

Two resources that provide information on these psychometric properties are the *Buros Mental Measurements Yearbook (MMY)* and *Tests in Print (TIP)*. TIP informs potential users of the purpose, publisher, price, administration time, and other factual information about commercially available assessments. MMY includes independent reviews of specific assessments by professionals with expertise in test construction and psychometrics. In addition to information on reliability, validity, and measurement error, the reviews generally include information about the population with whom the measure has been designed to be used.

Assessment Administration

A variety of potential limitations are related to those who administer an assessment and the conditions of the assessment session. Due to the differing levels of rigor and training needed to interpret assessments, many assessments are not available for general use. Instead, assessments are

given levels of classification, each level requiring increasingly rigorous training or supervision. Assessments that were developed for use in diagnosis decisions are most frequently given a high classification and are only to be used by professionals trained in that specialty.

In addition to training, the administrator of the assessment has duties to the children and adults being assessed. Spending time to build rapport can increase the cooperation and therefore the quality of interactions during an assessment. The timing of assessments may also impact the quality of the assessment. For example, children may demonstrate lowered capability when hungry, ill, or sleepy. As with any work with young children, attunement to cues is necessary. Relative to classroom observations, it is typically best to observe for longer periods of time involving several segments of the day rather than relying on a brief observation period involving just one activity or time span.

When conducting child assessments, the assessor needs to be thoroughly familiar with the test materials and how to present them to young children to ensure optimal child performance. In addition to skillfully administering items to the child, the assessor needs to accurately record responses and score the assessment. Practice and training are required to ensure engaging and accurate assessment administration that elicits a child's optimal performance.

Interpretation of Assessments

The earlier sections describe many potential threats that serve to limit the usefulness of assessments. However, a final limitation is the capacity of people charged with interpreting the results to do so in a knowledgeable and professional manner. This requires several professional competencies addressed earlier, such as knowing the purpose of the assessment, if the specific assessment design and technical properties match the desired purpose and relevant demographic characteristics, if the proper training and supervision were available to ensure proper and accurate administration and scoring, and finally an understanding of what the results mean and how to understand and use them

in the broader context of the child, family, and early childhood program.

ASSESSMENT OF PLAY

This entry discusses the use of play as a method of interpreting children's development. An alternative to standardized testing, play-based assessment is an authentic means of looking at a child's development, strengths, and needs. The entry first addresses why play assessment is needed, then moves into discussion of three different approaches with emphasis on the most comprehensive of the three. The three play-based models discussed include two structured approaches, one a standardized approach and the other a single domain approach, and one nonstructured, transdisciplinary play-based approach. These three models are currently widely used. Other play scales exist, but most are used in research studies.

Need for Play Assessment

With the passage of the Education for All Handicapped Children Act of 1975 and the Individuals with Disabilities Education Act (IDEA) in 1990, the identification and assessment of children with special needs who are younger than 5 became a priority. Building on the approach used with school-age children, a variety of standardized measures were identified or developed to serve this purpose. However, soon many professionals began to have doubts about the effectiveness of this traditional assessment method with younger children.

Young children have developmental characteristics that make administering a standardized test difficult, including a short attention span, shyness with strangers, and lack of motivation. Add to this the characteristics of young children who potentially have special needs and the issue of accurate assessment becomes even more challenging. Lack of language and/or social skills as well as fine motor concerns, repetitive actions, limited interests or unfocused attention all contribute to the potential for inaccurate assessment. Now add in children who come from non-Western cultures, children who speak different languages, children who come from backgrounds where they have not been

exposed to materials found in test kits, and the problems with assessment accuracy are compounded. Take two examples:

Child A is 3 years old. She is withdrawn with strangers, and though her mother says she does talk, she is quiet with the test administrator. She has a short attention span, has difficulty with fine motor control, and misses many items, such as puzzle and block construction, which require fine motor control. The resulting score reflects that Child A is 2 standard deviations below the mean in the cognitive area. In his report the psychologist indicates that this is not a totally accurate representation of the child's skills, but the child's score results in her being labeled with severe developmental delays.

Child B is 4 years old and from a bilingual family that lives in a low-income housing development. The family moved from Argentina to the United States 1 year ago. Child B has just entered preschool for the first time, and his teacher referred him for lack of language and poor social interaction skills. He is highly distractible and does not give the test administrator eye contact. A Spanish version of a standardized test is administered and the child is found to be 1.5 standard deviations below the mean in language. In addition, the tester feels that some of the child's characteristics might mean that he is on the autism spectrum, so he is referred for further testing for autism.

Both of these scenarios point to the reasons that alternative methods of assessment are needed. In the case of Child A, her shy temperament, lack of attention, and fine motor difficulties result in a low cognitive score. Many of the "cognitive" items on the test require fine motor or language production. Missing items lowers her cognitive score. In the case of Child B, the test used was translated from English into Spanish but was not standardized on children from Argentina. Add to this the cultural aspect of not looking at adults of authority, the child's lack of exposure to Western educational materials, and his distractibility, and the

results should be in question. Use of traditional assessment methods with young children increases the possibility of obtaining fragmented, inaccurate, or incomplete results.

Issues such as these have led parents and professionals alike to object to reliance on traditional methods that do not provide an authentic picture of the child's strengths and needs. Given that placement, program planning, and goals and objectives are determined from testing, much is at risk when mistakes are made. As many professionals have noted, standardized assessment procedures should be used with great caution in early education because such tools are inherently less accurate and less predictive when used with young children. In an effort to address the problems with traditional assessment, play-based assessment was developed.

Play-Based Assessment

Authentic assessment requires that the process through which assessment and evaluation information is gathered be obtained by observing the child engaged in real-life activities in relevant contexts. The results obtained from an authentic assessment should also inform real-life intervention approaches. Play-based assessment derives from the effort to create an ecologically based form of authentic assessment. It offers a valid way of addressing the diversity of backgrounds, cultures, and developmental differences found in young children. Play-based assessment is currently used as a means of identifying and diagnosing children who need special services, a process for determining intervention approaches and strategies, and a method for monitoring developmental growth and progress toward specific developmental objectives.

The advantages of play-based assessment are many (see Table 1). Play-based assessment involves children in an activity they already love. Children are inherently motivated to play and practice mastery in a fun way. Play is a universal language. All children, across all cultures play. What they play with and how they play differs, but all play involves movement, communication,

social interaction, and thinking. As such, play provides a holistic window into all areas of development. Play enables observers to see a child's strengths, preferences, and learning style. This information flows naturally into planning appropriate placements, goals, and intervention strategies.

Standardized Play-Based Assessment

One structured play assessment approach is Rebecca Fewell's Play Assessment Scale (PAS). This experimental and observational tool examines the perceptual and conceptual skills the child reveals through play under two different conditions, Condition I (spontaneous play) and Condition II (prompted play). The PAS can be administered in any comfortable setting, allowing for floor play by anyone familiar with the tool who has an in-depth understanding of child play behaviors.

The PAS contains 45 developmentally sequenced items and is designed for children aged 2 to 36 months. It contains eight age ranges and toy sets, so different materials are used for different age levels of children. The examiner selects four sets of toys: two that are appropriate for the child's estimated age, and one below and one above that level. Each child is given about four toy sets, but that number can vary.

Children are first observed in Condition I, spontaneous play. Toys are set on the floor and the child is allowed to play with just a few introductory remarks. The examiner avoids telling the child what to do with the toys. The examiner codes behaviors observed according to a scale. When the child starts repeating play behaviors or is not demonstrating more advanced play behaviors, the examiner moves into Condition II. In this situation, the examiner now tries to prompt the child to engage in higher level play, by inviting, suggesting, commenting, or directing. Notes are made about the child's behaviors and responses.

Only the observations made during the spontaneous play are used for scoring. The number of items credited between the basal and the ceiling

determines the raw score. A conversion chart then yields a "play" age. Information gained from the prompted play is used for discussing emerging skills and qualitative descriptions of successful elicitation approaches.

Advantages of the PAS. One person can administer the instrument in a short period of observation. There is some flexibility in materials selected for the child. It has evidence of validity when compared to other measures.

Disadvantages of the PAS. The tool has a limited age range and developmental focus. Only spontaneous play is scored. Parents are not involved in the process.

Play in Early Childhood Evaluation System

One of the most recent play assessment tools, developed from 1999 to 2005, is the Play in Early Childhood Evaluation System (PIECES) developed by Lisa Kelly-Vance and her colleagues. This cognitive assessment tool was based on the original version of Toni Linder's work, Transdisciplinary Play-Based Assessment (TPBA), and, similarly, is conducted in any setting with appropriate toys and materials. The child plays alone for 30 to 45 minutes without being required to play with any particular toys or materials. Parents and a session facilitator observe and can interact with the child but cannot suggest or direct play. Coding guidelines are presented for one core domain (exploratory/pretend play) with supplemental subscales for problem-solving skills and planning, categorization skills, quantitative skills, drawing skills, and seriation abilities. All play behaviors are coded on the 13-item sequence of exploratory/pretend play, whereas specific types of behaviors are coded on the supplemental domains. The information from the coding procedure is then compared to norms based on typical development to determine play levels and intervention targets.

Advantages of PIECES. Only one assessment administrator is needed and the time required is

Table 1 Comparison of Standardized and Play-Based Assessment

<i>Standardized Testing</i>	<i>Play-Based Assessment</i>
Assessment is an instrument	Assessment is a process
Norm sample based on a specific population	*Adjustments are made for background, culture, and language
Based on a medical, deficit model	Based on a strengths-based ecological model
Assessment information derived primarily from testing of the child	*Assessment information derives from the family, caregivers, and observation across settings
Some children are “untestable”	Every child is “testable”
Parents are not included in the testing procedures	*Parents collaborate in the process and are integral to the assessment
Same materials are used with all children	*Materials used depend on the interests, experience, and needs of the child
Same directions are used with all children, language is standardized	Language used depends on the level and background of the child
Assesses norm-referenced skills	Assesses functional skills, learning style, and underlying processes needed for progress
Adult-directed process	*Child-directed process with adult facilitation
Results are standard scores, percentiles, etc., based on statistics	*Results in developmental levels, range of ability, and cross-disciplinary analysis. Professional judgment is important
Information used for diagnosis and placement	Information used for diagnosis and placement, program planning, goal setting, and intervention strategies
Isolated assessment of discrete domains of “motor,” “language,” “cognition,” “social-emotional”	*Holistic observation of domains and transdisciplinary integration of data
Domain tests administered by separate professionals	Observations made as a team, including parents, so all observe the same behaviors
Does not include siblings or peers	*Includes siblings and/or peers
Goals derived from items missed	Goals derived from team analysis of skills and processes
Results validated by another standardized test	Results validated by family, caregivers
Often stressful for child and family	Less stressful as the process is fun and the family is part of the process

Note: Items with asterisk (*) indicate this is characteristic of Transdisciplinary Play-Based Assessment, second edition (TPBA2), not all play assessments.

less than 1 hour. The coding system is well researched and has high validity and reliability. The results lead to functional intervention targets.

Disadvantages of PIECES. The focus is only on cognitive development. The narrow focus may mask other concerns. No facilitation is used. This may reduce play of some children with special needs.

Transdisciplinary Play-Based Assessment, Second Edition

TPBA2 by Linder is the most comprehensive play assessment approach for children developmentally functioning from 1 month to 6 years of age. The process is transdisciplinary, meaning that it integrates information from a multidisciplinary team of professionals into a holistic picture of the child's functioning. TPBA was originally published in 1990 and revised in 1993. A total revision and update was completed and TPBA2 was published in 2008. TPBA2 makes the play-based assessment process a convergent process, including information from families, caregivers, and teachers. It includes seven subdomains for each of the domains (cognitive, emotional-social, sensorimotor, and communication, including a functional vision screening and simple hearing screening). Table 2 illustrates the complexity and comprehensiveness of the areas of development that can be observed in play.

A key component of the TPBA2 process is obtaining preliminary functional and historic information from parents and other caregivers. This information makes the assessment convergent,

bringing together insights and observations from key players in the child's life into the assessment process. The information is also used to help plan the actual play session. The TPBA2 takes place in any setting that is conducive to play. Material may be found in the home or provided in a playroom. Augmentative devices and toys are used when necessary to enable the child to engage in interaction and play. Members of the team from various disciplines each observe his or her area of expertise, but some also serve in an additional capacity in the TPBA process. One team member is designated as a play facilitator to play with the child, following the child's lead and scaffolding (modeling the activity) when needed to see the best the child can do. Another team member is designated as the parent/family facilitator, whose role is to obtain more information about how the child's current behaviors compare to what is typically seen, provide information about what the play behaviors mean to them, elicit the parents' interpretation of language and behaviors, and involve the parent in playing with the child. It is also recommended that the play session be videotaped for later review.

TPBA2 includes qualitative guidelines or questions for professionals to answer when observing

Table 2 Domains and Subcategories of TPBA2

<i>Sensorimotor Development</i>	<i>Emotional-Social Development</i>	<i>Communication Development</i>	<i>Cognitive Development</i>
Functions underlying movement	Emotional expression	Language comprehension	Attention
Gross motor activity	Emotional style/adaptability	Language production	Memory
Arm and hand use	Regulation of emotions and arousal states	Pragmatics	Problem solving
Motor planning and coordination	Behavioral regulation	Articulation/phonology	Social cognition
Modulation of sensation	Sense of self	Voice and fluency	Complexity of play
Sensorimotor contributions to self care	Emotional themes of play	Oral mechanism	Conceptual knowledge (math and science)
Vision	Social interactions	Hearing	Literacy

the child. The questions relate to *how* the child performs and how much and what type of support the child needs across domains. Each domain also has age tables that enable professionals to determine the range of a child's skills (basal to ceiling) and the age level where most of the child's skills cluster. Using the cluster age, the child's percentage of delay is determined. This is often a score that is used for eligibility. The process also includes Transdisciplinary Play-Based Intervention, second edition (TPBI2), also developed by Linder in collaboration with colleagues from different disciplines. TPBI takes information from the assessment findings and directly relates these to specific intervention suggestions and strategies for home and school. The process can also be used to measure progress over time.

Advantages of Transdisciplinary Play-Based Assessment. TPBA2 is a comprehensive, holistic process that integrates parents' and professionals' perspectives into functional findings and intervention recommendations. Research findings show high concurrent validity, social validity, and reliability. Play facilitation allows the team to see the best the child can do and determine what supports are needed. TPBA is easily adapted to different cultures.

Disadvantages of Transdisciplinary Play-Based Assessment. A team of at least two members is required, and three or four team members are preferred. The entire assessment process takes 1.5 to 2 hours. The age tables are research-based, not normed on a specific population.

Conclusion

The past 2 decades have seen ever-increasing awareness of the importance of early childhood education and intervention for children from birth to 6 years of age. We now know that both early education and early intervention can have long-term positive impacts on both the children who participate and their families. Consequently, we need to be able to identify children who need

extra supports at the earliest age possible. Traditional assessment measures are inappropriate for the majority of children with special needs, children with diverse cultural and linguistic backgrounds, and children who are at risk because of adverse environmental concerns. Play-based assessment provides an authentic alternative that enables professionals to observe children's holistic development when they are motivated and engaged in something they love to do. The qualitative and quantitative information that is gained translates directly into program planning and intervention strategies. With additional recognition of the benefits of play-based assessment, it is hoped that state and local requirements will adjust to the needs of young children and make room for more authentic approaches to identification of young children with special needs.

ASSISTIVE TECHNOLOGY IN EARLY INTERVENTION

Assistive technology (AT) in early intervention is defined as any item that helps increase the independence and functioning of an infant or toddler who has a disability. AT can assist with communication, positioning and mobility, play and interaction, self-help, skills development, and learning. AT is often low tech and low cost, involving simple adaptations such as utensils with built-up handles for ease of holding and manipulation. High-tech AT devices such as wheelchairs, standers, and augmentative communication devices are more sophisticated, specialized, and costly.

AT also includes toys purchased at local stores that are adapted to help children with disabilities play more independently and participate in daily routines. AT may also include any service that assists children and their families select, acquire, and implement appropriate AT for the needs of the infant or toddler.

Scholars such as Sharon Judge and Elizabeth Lahm have argued that AT can increase young children's options and facilitate their physical and social inclusion in various settings. It can provide support for cognitive processing or enhancing memory and recall, and it promotes learning and development by assisting infants and toddlers in more effectively participating in activities and routines in their natural environment. When used thoughtfully with the infant or toddler by practitioners and family, AT can be empowering, increasing early independence and supporting inclusion involving natural participation in play.

Research into the effectiveness of AT for infants and toddlers is still in its infancy. The National Association for the Education of Young Children maintains that continuing research is needed to better understand how infants and toddlers use and learn with AT and to better understand its short- and long-term effectiveness so as to inform policy makers and early intervention providers interested in issues of access and equity for infants and toddlers, parents, and families within what is

known as developmentally appropriate practice (DAP) in early childhood. Enhancing future efforts for AT in early intervention is a team effort, with families being closely involved. When early intervention providers appropriately procure and integrate AT, equity and access are addressed by providing opportunities for all children to participate and learn.

In practice, AT is often used by early intervention practitioners as a distracter. A practitioner may, for example, use the child's motivation to interact with a toy as a way to position him or her longer on his or her stomach or to shift weight from side to side. Sensory and cognitive skills are often targeted using AT during focused skills development. For instance, toys are provided that encourage a child to use both hands to manipulate an object, or "play" is designed to strengthen bilateral hand coordination, which can then be used in higher level play activities. The goal in such early intervention practice is to improve developmental skills that, in turn, will increase the quality and quantity of the play interactions so an infant or toddler with a disability can perform on a par with his or her nondisabled peers.

Many of the skills learned in life begin in infancy, and AT can help infants and toddlers with disabilities learn many of these crucial developmental skills. Communication skills are especially important in infancy and toddlerhood as infants and toddlers learn through interacting with family members and other primary caregivers. Parents may be reluctant to begin using an AT device, believing it may discourage their child from learning crucial skills. Research, however, has shown that using AT devices, especially augmentative communication devices, may encourage a child to increase communication efforts and skills. Moreover, the earlier a child is taught to use an AT device, the more easily the child will learn to accept and use it.

Intervention focused on facilitating playfulness emphasizes the quality of a child's play with the child guiding play to incorporate motor, sensory, language, creative, and cognitive skills in a holistic manner without focusing on any specific goal or

skills. AT addresses barriers that exist by affording the infant or toddler the opportunity to initiate and sustain playful activity at the appropriate developmental stages of play.

As AT becomes more readily available for early intervention, further research is needed on what infants and toddlers are able to do with AT and how AT can be integrated successfully into the natural environment to promote the skills development of infants and toddlers with disabilities not only through therapeutic interventions but also during natural, child-initiated, and guided play-based experiences. Early intervention providers and parents must take time to select and evaluate AT and observe the infant or toddler as he or she uses the devices to become familiar with the various options and make appropriate adaptations.

A survey of early intervention providers by M. Jeanne Wilcox, Amy Guimond, Philippa H. Campbell, and Heather Weintraub Moore published in 2006 identified areas of AT practices in early intervention that should be strengthened. Of great concern is that only 18% of providers viewed themselves as well trained or as having a lot of knowledge about AT for infants and toddlers with disabilities. Several tensions and barriers have been found in the literature that may account for limited AT use in early intervention—namely, the dichotomy between therapy and play, family and provider beliefs about using AT, funding issues, the availability of AT devices, a lack of providers who are trained in the use of AT devices, and attitudinal barriers (e.g., negative images or a fear of technology). Scarce use of AT may also be attributed to the relative newness of AT with infants and toddlers and a lack of research examining the selection, use, and efficacy with this population of children. Research-based evidence about what constitutes quality AT for play-based learning is needed to guide policy and inform practice and to ensure that AT is used in effective, supportive, engaging, and appropriate ways in infant and toddler play-based programs in natural settings. Irrespective of severity of disability, all children have some capacity to engage in play and AT can assist children in a broad range of play activities.

All too often natural play for children with disabilities may be diminished or absent, yet play is important for all children, including those with a cognitive delay who may be thought of as being disinterested in play. Early intervention providers and parents need to develop their awareness of how to nurture the development of a child with a disability through play with AT because it can make play accessible for infants and toddlers with disabilities.

AT plays a crucial role in increasing accessibility and opportunities for developing all aspects of early play. The environment for play, for example, the lighting, noise levels, and modifications of space and accessibility, affect play. A supportive pillow such as the Boppy, for example, may allow a young child to be more upright; an infant with very low muscle tone may be unable to reach out efficiently to interact with his or her environment. There are also other positioning items that allow the child to move, bounce, and/or turn in place. Everyday low-tech AT materials such as cardboard boxes, car seat head positioners, towels, pillows, and cylinders can be used to position children.

Children need to move to explore their environments within play. AT devices are available that encourage and support children to move. These are commercial walkers, rocking and riding toys, climbing and sliding equipment, and well-designed swings. Switches, adapted battery-operated toys, and interfaces make it possible for children to turn a toy on and off with a movement of a body part against a switch. Single switch use can also be applied to motorized scooters that give the child the opportunity to move through space independently at a young age. Adapted computerized peripherals and appropriate software for children can be adapted. A single switch that reduces control to a single key or the use of a touch window may be the most appropriate input devices for this population. Some communication devices can act as a switch interface to include a message heard when the toy is activated. This strategy is frequently used to enhance opportunities for pretend play for young children with disabilities.

A simple box easel can allow a toddler to participate in creative activities such as painting and drawing by moving paper to a vertical surface. A toddler may find a book more engaging when it is clipped to an easel rather than lying flat on the table. A carpet square can become a ply mat for a child. Cars and blocks can be attached to the carpet so they won't roll away when played with. The use of a well-placed switch (a device attached to a toy that allows the child to interact in play by pressing) makes the toy accessible to a child who may not otherwise be able to make the toy move or make noise. Susan Mistrett, Shelly Lane, and Amy Goetz, in a 3-year federally supported project that worked to promote play in infants and toddlers with disabilities through the use of low-tech AT conducted in 2000, found that to build interest in electronic toys, toddlers can begin with highly reactive toys that provide immediate and intense reaction when touched. In summary, early intervention services that include AT must be provided in natural environments to the extent appropriate for the individual infant and toddler. This would include the child's home, child care setting, or other community settings with nondisabled infants and toddlers. As a part of the decision-making process around AT, the team should discuss where AT devices and services will best meet the child's skills needs developmentally and at the same time create crucial opportunities for the development of play with interactions for infants and toddlers with disabilities in natural settings.

AT-RISK FAMILIES

Risk is considered any factor that leads to a negative consequence. Indeed, there are many factors that place children and families at risk for poor outcomes, such as adverse health conditions, or violence within romantic and parent-child relationships. Such consequences can negatively impact a child's emotional, cognitive, social, and physical development as he or she transitions into adolescence and adulthood. This entry examines contemporary theory and research on a number of individual, family, and neighborhood stressors that place families at risk for a host of negative outcomes. These stressors include but are not limited to behavioral problems, substance abuse, depression, harsh parenting, life stress, economic distress, and mental illness across the life span. This entry also explores the term *resilience*, which describes processes or mechanisms that help children overcome significant adversity in their lives.

Theory

Many theories have been formulated to address factors that place families at risk for negative social and behavioral outcomes. For example, systems theory maintains that family influences are multidirectional where children influence their caretakers and caretakers influence their children. Sociocultural theories stress that norms within a particular peer group or culture influence behavior. It may also be the case that a way a person behaves is due to his or her genetic makeup, rather than solely being the result of the environment. However, one prevailing paradigm to explain risk derives from Urie Bronfenbrenner's bioecological model, which states that behavior should be reviewed within the context of nested environmental systems. Two other common explanations for risk include Rand Conger's family stress model (FSM), and social learning theory.

The bioecological model postulates that children and families function within a series of layered environments, each having an effect on development. The microsystem component of the model

contains factors within a child's immediate home environment that induce or inhibit development. The mesosystem is the relations among the various environments such as the association between the child's home and school settings, and the exosystem includes the larger community in which the child lives. Finally, the macrosystem layer consists of society ideologies and broad cultural values such as general views about children and parents in society. This also includes views about aggression and violence within a particular culture.

The FSM suggests that economic hardship leads to felt economic pressures for parents such as unmet material needs (e.g., inadequate food or clothing), the inability to make ends meet, and having to cut back on expenses (e.g., health insurance). This pressure places parents at risk for emotional distress such as depression, anger, and anxiety. These emotional problems lead to increased conflict between parents. These disruptions in the couple relationship spill over into interactions with children and lead to harsh and inconsistent parenting. These outcomes, in turn, threaten the social and emotional well-being of children.

The social learning theory posits that children learn through observing the interactions and behaviors of others. Thus, children who observe conflict between parents or experience harsh parenting within the family of origin model that same behavior to their own family members in adulthood. For example, children learn to behave harshly toward a romantic partner by watching their parents interact with each other in that manner. Likewise, children who are abused at the hands of their parents often grow up to abuse their own children as adults. This socialization perspective is often referred to as the intergenerational transmission of aggression or violence.

Risk Factors

Researchers have established numerous factors that place families at risk for negative health and behavioral outcomes. Furthermore, it has been found that a combination of risk factors, rather than any single factor, place children and families at an increased risk for adversity. Various individual-, family-, and

neighborhood-level risk factors influence child development and positive family functioning.

Individual Factors

Both child and parental characteristics have been linked to negative outcomes. For children, one common risk factor for child maltreatment is age: Younger children are more likely than older children to be maltreated by their caretakers. This can be best explained by stress associated with the constant care required for parenting young children. Other child risk factors for outcomes such as abuse include irritable or difficult temperamental dispositions, behavioral problems, and intellectual or physical disabilities. For children with disabilities, the stress associated with caring for their needs, economic stress from health care expenses, and the strain on marital relationships from factors such as disagreements about care increase the likelihood for abuse.

There is also research to suggest that child behavior may influence the type of parenting a child receives. In other words, a child who displays problem behaviors or has a difficult temperament may elicit harsh punishment from parents. For example, children who are high in externalizing behavior intensify poor parental monitoring or discipline and may also become harsh parents themselves. It should be noted that these child factors do not suggest that children are to blame for poor outcomes. These qualities simply put the child at greater risk for consequences such as abuse.

In terms of parental risk factors, substance use, including drug and alcohol use, and symptoms of mental health problems, such as depression or anxiety, have been associated with negative outcomes such as child maltreatment. For these parents, compromised judgment and poor decision making may be causes for abuse. Other risk factors include personality types such as negative emotionality and anti-social behaviors including hostility, delinquency, externalizing behaviors, and conduct problems. In addition, parents who have unrealistic expectations for their children or who view their children more negatively may be at higher risk for abusing them. Because it is impossible for children

to live up to such high expectations, parents may be even more sensitive to their child's negative behavior and less likely to view their behavior as being positive. Moreover, they may view their child as being more intentional in their negative behavior and more difficult to control.

Many of the previously mentioned risk factors have also been shown to be consequences for children as they develop through the teen and adult years. For example, predictors such as substance use and depression are potential outcomes for children. Poor self-concept, eating disorders and weight management problems, and school problems are also examples of potential consequences of growing up in a risky family environment.

Family Factors

Harsh discipline or psychologically abusive parenting is one of the most consistent risk factors for a host of negative consequences for children. In the short term, harsh or hostile parenting may be related to physical and psychological injuries, as well as higher levels of problem behavior during childhood. As children grow to adulthood, harsh parenting received in the family of origin has been linked to obesity, substance use, risky sexual behavior, mental health issues, delinquency, being victims of intimate partner violence, and maltreatment of their own child. Indeed, as adults, children with a history of harsh parenting tend to emulate this type of parenting because these early experiences may exacerbate tendencies toward anti-social or aggressive conduct in general. That is, hostile parenting may be related to aggressive behavior during childhood. In turn, higher levels of aggressive behavior during childhood may be linked to higher levels of hostile parenting years later during interactions with their own children. Thus, there is suggestive evidence that an important mechanism linking harsh parenting across two generations is risk for emotional and behavioral problems by children raised in a hostile family environment. These markers of maladjustment appear to carry forward to disrupt parenting behavior in the second generation.

Evidence also suggests that parenting practices influence later romantic relationships, perhaps

even more so than marital or sibling interactions within the family of origin. Through parent socialization practices, children learn communication strategies, problem-solving skills, and conflict-resolution strategies. When parents are hostile or harsh in their interactions with children, it may make it difficult for the child to establish healthy and satisfactory romantic relationships as an adult. For example, children who experience angry and criticizing parents tend to display similar behavior toward their own romantic partner throughout adulthood. Similarly, distant parent-child relationships during childhood may be linked with a child's romantic relationship quality in young adulthood that is characterized by jealousy and emotional extremes. Taken together, low-quality parent-child relationships are an important catalyst of low-warmth and high-conflict romantic relationships in adulthood.

Another common risk factor for adversity is the intergenerational transmission of partner violence or exposure to intimate partner violence in the family of origin. In particular, it is common for children to both witness intimate partner violence and be victims of parental abuse at the same time. Indeed, when children are exposed to intimate partner violence, there is an increased likelihood that during adulthood they will be involved in violent romantic relationships and will mistreat their own children. For example, boys who witness domestic violence are at greater risk for growing up to beat their own partners. Competencies that promote a child's successful and positive adult romantic relationship may be traced to family experiences during childhood through the social learning hypothesis, which suggests that the behavioral interactional styles that were frequently modeled and reinforced in the family of origin (i.e., marital relationships) will be imitated by the adult children in their later close relationships.

In addition to harsh parenting practices or witnessing violence within parental relationships, exposure to stress has been explored as a predictor of adverse consequences such as family violence. For example, life stressors, work, and parenting stress have all been associated with marital conflict

and higher rates of family malfunction. In addition, families that are characterized as being chaotic or having higher rates of conflict put children at risk for poor developmental outcomes.

Finally, families who are socially isolated, experience loneliness, or have fewer resources for social support are at greater risk for violence than families who have access to such resources. For example, parents who have fewer friends or minimal contact with friends or family members may be more likely to maltreat their children than those who are more socially active.

Economic Risk Factors

In addition to the intergenerational transmission of aggression and violence within relationships, there is accumulating evidence that economic adversity may persist across generations. One possible explanation is that parents transmit skills, knowledge, and character traits that help determine their child's potential work earnings as an adult. It may also be that economic hardship as experienced in the family of origin diminishes a child's educational attainment as well as parental investments in college. Therefore, there is reason to believe that children who grew up in an economically disadvantaged household may face their own financial hardships as adults.

Economic deprivation, whether the result of chronic poverty or a sudden economic downturn, can negatively impact children and their families through emotional problems, marital distress, problems in parenting, and child maladjustment. For example, parents who can't afford basic needs may have higher levels of depressive symptoms, which can lead to problems in parenting that, in turn, are related to decreases in child positive behavior and increases in problematic behavior. Indeed, children growing up under conditions of economic hardship are at increased risk for emotional and behavioral problems, a decrease in social competence, lower cognitive abilities, and elevated physiological markers of stress. Living under economic strain may also affect a child's personality in that he or she may be more likely to

be high on traits such as negative emotionality and low conscientiousness. Likewise, exposure to poverty during childhood places youth at increased risk for dropping out of school, engaging in risk-taking behavior, and entering parenthood at an early age.

In addition to economic hardship, families who suffer from lower levels of completed education, unemployment, or low income may put children at higher risk for negative developmental consequences. For example, less educated parents are more likely to maltreat their children than more highly educated parents. Low parental education, parental unemployment, limited income, and financial strain have all been related to poor health outcomes in children, such as obesity, as well as teen dating violence and other externalizing or delinquent behaviors.

Demographic Family Factors

Several family demographic factors have been linked to negative family outcomes. In terms of marital or relationship status, single-parent families and families with one nonbiological parent place children at greater risk for maltreatment. Indeed, the rate of child abuse for children raised in single-parent households is double that for those raised in two-parent families. Similarly, incest rates are higher in stepfamilies given the lack of a biological relationship between parent and child. Age and gender may also be risk factors in that children born to mothers who begin childbearing at a young age experience a variety of negative outcomes. For example, teenage female parents seem to be a greater risk for utilizing harsh parenting practices compared with older mothers. Reasons include their developmental age, lack of knowledge about appropriate discipline, and the inability to handle stress. Teenage parents are also more likely to have other risk factors for abuse, such as being single, unemployed, and less likely to have graduated from high school. Children born to teenage parents may be at increased risk for externalizing problems, drug use, and entering early parenthood themselves.

Neighborhood Factors

During the past decade, research has focused more attention on neighborhood-level risk factors. Indeed, work has shown that children exposed to neighborhood violence are more likely to perpetrate later violence than children who are not raised in such an environment. This may be due to poverty that is found within dangerous neighborhoods or the view that violence is an acceptable response to conflict. Similarly, perceived low neighborhood quality has been positively associated with later problem behaviors. For example, neighborhoods that are mainly comprised of single-parent families, are high in deterioration, or have inadequate resources place families at greater risk than those neighborhoods considered to be of higher quality. Also, neighborhood collective efficacy and connectedness have been established as a potential protective factor for children and families.

Resilience to Family Risk

Not all children who grow up in a negative environment become aggressive or hostile in their relationships with others. Having access to social support or necessary resources may help to protect those families who may be considered at risk. For example, children who were abused within the family of origin may be less likely to abuse their own child if they have access to services such as parenting classes or counseling. It may also be that positive personal characteristics or having positive relationships help to buffer the negative impact of a risky home environment. That is, children who have a positive relationship with a non-maltreating caretaker, or have support from teachers or peers, may be protected from the negative consequences of maltreatment.

Moreover, stable, nurturing, and supportive behaviors of a spouse or cohabiting romantic partner may strengthen co-parent relationships and help break the intergenerational cycle of harsh parenting. It has been found that romantic partners who are warm and engage in positive communication patterns appear to disrupt continuity in harsh and abusive parenting. Thus, as appropriate,

preventive interventions designed to reduce risk for child maltreatment should include a focus on spousal or partner behaviors in their educational or treatment programs.

In terms of economic adversity, there is considerable variation in how children and families respond to economic hardship. That is, although there may be an association between economic adversity and negative family functioning, some families are able to adapt and function well in spite of experiencing economic hardship. Couple interaction and parenting behaviors may play a critical role in mediating the effects of economic disadvantage on child outcomes. Parents who are able to maintain effective parenting skills, even in the face of adversity, might have children who are more resilient.

Maintaining a sense of positivity might be one personal characteristic that can help facilitate resilience to economic hardship. Positivity is the tendency to view life and the future with confidence and a positive outlook. It includes having a high level of self-esteem, life satisfaction, and optimism about various life and situational experiences. These elements of positivity may contribute to important individual- and family-related outcomes. For example, having a high self-esteem influences important life outcomes such as relationship and job satisfaction, depression, and physical health. In general, those who display a positive outlook, or a sense of optimism and mastery, seem to have better life outcomes.

In sum, it may be that a combination of individual and family resilience processes lead to positive adaptation to risk. If children and parents have personal resources to cope in the face of adversity, they may possess greater ability to maintain skills that lead to positive outcomes for children. Likewise, positive communication patterns between couples as well as the effects of positive parental disposition may have lasting positive impacts for children and families at risk. Thus, interpersonal processes may serve as an important target of intervention and prevention efforts designed to promote positive child development over time.

ATTACHMENT AND STRESS

For healthy development to unfold, a child needs supportive, reliable relationships with adults. *Attachment theory*, originating in the work of John Bowlby, examines how early social interactions contribute to a child's later functioning. This theoretical model has generated important research exploring the dynamics and developmental significance of a child's relationship with primary caregivers. More recently, attachment theory has been extended to stress research in order to elucidate how attachment figures regulate the activity of stress-responsive hormones and protect

the developing brain and body from their potentially deleterious effects. This entry first defines attachment theory, then discusses the role of attachment relationships in regulating stress. It then discusses how researchers study attachment and stress, some key research questions, recent research results, and gaps remaining in the understanding of attachment and stress.

Attachment theory provides a conceptual framework for stress research to understand (a) how positive social relationships can serve as stress buffers for children, and (b) how attachment figures shape the development of a child's stress response systems. Through attachment theory we can gain insight on how interactions with trusted, sensitive caregivers establish a foundation for lifelong physical and mental health.

Stress is a normal part of life, and some amount is necessary for healthy development. Through early experiences of positive, manageable stress, children can learn important coping skills. However, when nurturing relationships are impaired by situations such as parental substance abuse or severe depression, or children are in situations when attachment figures are a source of threat because of abuse, children are not able to manage stress by themselves. Under these conditions, stress hormones and neurochemicals may be frequently or chronically activated resulting in toxic stress impacts that enhance the risk of poor physical and mental health.

Research has begun to identify the mechanisms by which exposure to severe early life stress (ELS) can have deleterious effects on health and development. Although there have been significant advances in understanding the physiological mediators of the stress response, less is known about their neurocognitive correlates. Attachment theory has provided a fruitful framework for investigating social, cognitive, and physiological factors of the stress response, allowing us to move toward a more complete understanding of how stress influences the development of the brain, behavior, and health. This knowledge will help identify intervention and prevention targets, with broad implications for policy.

The Stress-Regulating Role of Attachment Relationships

Research shows that a child's attachment relationships with adults shape the development of the stress response system and thereby have a profound effect on later health outcomes. Stress can be defined as the biological or behavioral responses to experiences that challenge an individual's physical or psychological welfare. The stress response integrates several biological systems including the *sympathetic nervous system*, the *neurotransmitter systems*, the *immune system*, and the *hypothalamic-pituitary adrenocortical (HPA) axis*.

The HPA axis, which maintains an organism's capacity to respond to acute and chronic stressors, is a primary focus of child development research. Stressors activate the HPA axis, which results in the production of stress hormones called glucocorticoids, including *cortisol*. ELS can disrupt brain development through the repeated and prolonged exposure to elevated cortisol and/or to *corticotropin-releasing hormone (CRH)*, a related component of the stress response.

This overexposure to stress response hormones and neurochemicals may induce a hypersensitization of neural circuits that process threat information. Additionally, ELS can compromise the functioning of the nervous and immune systems. Chronic activation of the HPA axis can contribute to *glucocorticoid resistance*, which causes immune cells to become "deaf" to a cortisol signal that would otherwise have anti-inflammatory effects. This leads in turn to increases in both cortisol and inflammation that over time are associated with risk for physical and mental health disorders. Overall, the neurobiological consequences of ELS promote short- and long-term problems that undermine healthy development.

Originally, attachment theory was focused on how early social relationships influenced the development of a child's affective regulation. Today, researchers use a neurobiological perspective to extend insights from attachment theory toward an understanding of how early social relationships influence the development of a child's stress regulation system. Two core concepts guide attachment

theory research: (1) The caregiver-child relationship functions to help regulate the child following threatening events, and (2) early relationships shape a child's *internal working model* of the world, which subsequently operates throughout the life span to influence how an individual perceives and copes with threat.

Attachment theory predicts that infants who experience responsive, sensitive parenting are more likely to be *securely attached*. Infants with this attachment style feel secure in the presence of their caregiver and maintain proximity while using this adult as a "safe base" from which to explore. When the parent is low in sensitivity or inconsistently responsive, children are more likely to exhibit an insecure attachment style. *Insecurely attached* children fail to develop feelings of security from the attachment figure. As a result, these infants behave more independently or ambivalently toward their caregiver, both physically and emotionally. They do not orient to this adult while exploring, and they explore less overall. Maltreated children's attachment patterns are often disordered and disorganized and, in extreme cases, meet classification for reactive attachment disorder.

One problem for researchers studying attachment and stress in children is the complex and multifaceted nature of these topics, in addition to the dynamic and bidirectional influences they may have on each other. For example, there are multiple factors researchers must consider when examining the effects of stress on development; these factors include (a) the type(s), chronicity, and severity of stressors a child faces; (b) the effects of developmental timing of exposure; and (c) individual biological differences in reactivity. In the context of examining psychological mechanisms of coping with stress associated with attachment, researchers also must consider (a) individual differences in variations in the primary caregiver-child relationship, (b) continuity and change in relationship attachment quality across development, (c) the influence of developmental status on how attachment relationship effects manifest in behavior, and (d) the role of inherited genetic factors in shaping attachments.

Research Context

Technology

To study young children, physiological measures of stress must be noninvasive. Cortisol can be measured in small samples of saliva, which makes study of the HPA axis highly tractable. Saliva can also yield an indirect measure of activity of the sympathetic nervous system (alpha-amylase). Otherwise, the sympathetic or fight-flight aspect of stress biology requires electrophysiology and measures of heart rate or galvanic skin responses. Although noninvasive, these procedures are subject to movement artifact, which may mean the child needs to sit quietly. There is growing interest in studying oxytocin, a hormone involved in promoting proximity and contact with relationship partners. Whether it can be measured accurately in saliva is controversial; cautious researchers assess it in urine. With regard to assessing attachment quality, two methods are used: the *Strange Situation* test and the *Attachment Q-Sort*. Both assess the extent to which the child uses the parent as a secure base. One challenge of attachment research is the limited number of validated indices of attachment security, as well as the limited age period during which these assessments are valid.

Translational Research

Animal research has played a critical role in driving the investigation of attachment and stress. Rodent and nonhuman primate studies have provided impactful insights on the effects of early social deprivation on stress physiology.

Key Research Questions

In research on attachment theory, some key questions are as follows:

1. What are the biological bases of attachment?
2. How do social relationships "buffer" or regulate the HPA reactivity?
3. How are the developing stress systems and their integration shaped by early life care?

Recent Research Results

To extend attachment theory to the study of stress, researchers have utilized animal models to examine the physiological systems underlying attachment behavior. We now know from animal research that core features of maternal caregiving, such as feeding and tactile contact, play a primary role in an offspring's development by functioning as "hidden" regulators of the stress response system. This is powerfully seen in results demonstrating that even while anesthetized, a mother rat can reduce the stress response of her pup, via her physical presence. Importantly, the influence of a parent in reducing an offspring's stress response reflects the attachment the young have for her. For example, titi monkey infants demonstrate a greater attachment to their father than their mother, and accordingly, the father is most effective at reducing the infant's cortisol levels in response to a stressor.

This line of animal research has given rise to important insights on how interactions with parents help shape human children's stress response. As in animal models, the HPA axis comes under social regulation in human children. Adults can reduce a child's cortisol levels in response to stress through their mere presence and proximity. This phenomenon has been termed parental *social buffering*. Notably, stress buffering is more complete in secure than insecure attachment relationships.

Early social interactions with attachment figures also facilitate a child's ability to cope with stress by shaping stress response neural circuits in the developing brain. Situations involving severe deviation from the typical caregiving environment provide evidence of the importance of early nurturing for HPA axis functioning. Children adopted from institutions for orphaned or abandoned children provide important insights on the effects of social deprivation. Infants and toddlers living in such institutions exhibit an atypical pattern of blunted diurnal cortisol production. This pattern is characterized by cortisol levels that are low early in the morning and do not decline in the late evening. Notably, these findings are parallel to those examining diurnal cortisol production in rhesus monkey infants raised on cloth surrogates. Years

after removal from institutional care, some children continue to show blunted cortisol patterns. These data suggest that the lack of a reliable, sensitive caregiver early in life may disrupt HPA axis functioning and have persistent effects throughout development.

Research Gaps

Whereas we have strong evidence of social buffering effects in mother-infant dyads, few data exist examining social buffering effects at intermediate stages of development, such as juvenile (around 7 to 11 years old) and adolescent children. However, emerging research suggests that adolescence may be a time when attachment figures become less effective buffers of the HPA axis, although teens still derive emotional support from parents. Further research is needed to determine how social stress buffering dynamics change from adolescence to adulthood.

More work is needed to examine the underlying mechanisms of social buffering of stress-induced cortisol release. While some recent animal models suggest a role for olfactory and somatosensory sensory factors, translational work is needed to identify mechanisms of social buffering effects in humans. Oxytocin, a hormone shown to be important to both social relationships and the functioning of the HPA axis, is one promising candidate for future research.

Finally, we are beginning to understand how early social experiences can become biologically embedded and exert a profound influence on health and development. Recent animal and human research suggests epigenetic mechanisms play a significant role. Rodent models show that social deprivation increases the reactivity of the HPA axis through epigenetic modifications in the glucocorticoid gene. More research is needed to advance our understanding in this area.

Conclusion

For better or for worse, early social experiences have a pervasive and persistent influence on a

child's development. The impact of a healthy and secure attachment is illustrated by research showing that social interaction profoundly influences HPA axis activity in humans and other animals. Notably, the social regulation of the HPA axis is moderated by attachment style. For securely attached infants, caregivers are able to completely buffer the stress response, whereas for insecurely attached infants, stress-related cortisol increases are observed even when caregivers are present. Further research is needed to advance our understanding of the mechanisms underlying social buffering effects on the stress response.

These data provide support for the importance of safe, secure care for children. Positive early social interactions with adults can improve children's health and well-being both short and long-term, facilitating the development of healthy future citizens of our society.

ATTENTION-DEFICIT/ HYPERACTIVITY DISORDER

The United States Centers for Disease Control and Prevention (CDC) reports that 5.9 million children in the United States between 3 and 17 years of age have been diagnosed with attention-deficit/hyperactivity disorder (ADHD). These numbers make it the most common neurodevelopmental condition in the United States. The most common symptoms of

ADHD include an inability to focus, fidgeting or squirming, avoiding tasks or not being able to complete them, and being easily distracted.

This entry first defines ADHD. Next it covers how ADHD is diagnosed and concludes with current treatments, including behavioral approaches, and incorporating strategies for both families and early childhood educators working with young children at risk for or diagnosed with ADHD. The last treatment discussed is pharmacological intervention.

Definition

The criteria for identifying ADHD, listed in the fifth edition of the *Diagnostic and Statistical Manual of Mental Disorders* (DSM-5), are characterized by a pattern of behaviors resulting in academic and/or behavioral problems across multiple settings for social, educational, and employment interactions. According to the DSM-5's definition, the symptoms must be observed over time and across multiple settings. The DSM-5 did not revise the behavioral criteria from the DSM-IV, but it did increase the upper age limit for age of onset from 7 to 12 years of age—based on research that shows that ADHD can be identified later in life.

The criteria listed in the DSM-5 for ADHD are very specific. The CDC website presents a shortened version of the criteria that details ADHD's behavioral symptoms and outlines two general types of ADHD that occur—one with more symptoms of inattention and one with more symptoms of hyperactivity and impulsivity (CDC, n.p.).

1. Inattention: Six or more symptoms of inattention for children up to age 16, or five or more for adolescents 17 and older and adults; symptoms of inattention have been present for at least 6 months, and they are inappropriate for developmental level.
 - Often fails to give close attention to details or makes careless mistakes in schoolwork, at work, or with other activities
 - Often has trouble holding attention on tasks or play activities

- Often does not seem to listen when spoken to directly
 - Often does not follow through on instructions and fails to finish schoolwork, chores, or duties in the workplace (e.g., loses focus, gets side-tracked)
 - Often has trouble organizing tasks and activities
 - Often avoids, dislikes, or is reluctant to do tasks that require mental effort over a long period of time (such as schoolwork or homework)
 - Often loses things necessary for tasks and activities (e.g., school materials, pencils, books, tools, wallets, keys, paperwork, eyeglasses, mobile telephones)
 - Is often easily distracted
 - Is often forgetful in daily activities
2. Hyperactivity and impulsivity: Six or more symptoms of hyperactivity/impulsivity for children up to age 16, or five or more for adolescents 17 and older and adults; symptoms of hyperactivity/impulsivity have been present for at least 6 months to an extent that is disruptive and inappropriate for the person's developmental level.
- Often fidgets with or taps hands or feet, or squirms in seat
 - Often leaves seat in situations when remaining seated is expected
 - Often runs about or climbs in situations where it is not appropriate (adolescents or adults may be limited to feeling restless)
 - Often unable to play or take part in leisure activities quietly
 - Is often "on the go" acting as if "driven by a motor"
 - Often talks excessively
 - Often blurts out an answer before a question has been completed
 - Often has trouble waiting his or her turn
 - Often interrupts or intrudes on others (e.g., butts into conversations or games)

Children with ADHD can manifest primarily the inattention form of the disease or the hyperactivity/

impulsivity form, or they can present with a third form that combines behaviors from both categories. Boys experience higher rates of the mixed inattention and impulsivity form of ADHD, whereas girls demonstrate higher rates of inattention only. Because symptoms can change over time, the presentation may change over time as well.

Cause and Diagnosis

Researchers believe ADHD is a complex condition with varied and multifactorial risk factors. The CDC list of risks includes brain injury, environmental exposures (e.g., lead), maternal alcohol and tobacco use during pregnancy, premature delivery, and low birth weight. ADHD often runs in families, and genetic links continue to be studied. Research thus far estimates that 76% of cases have a hereditary link.

When diagnosing ADHD, a psychologist, psychiatrist, or pediatrician would look for the behaviors contained in the DSM-5 criteria for ADHD; the DSM-5 lists several other conditions that also must be met involving the age of onset of symptoms and their presence in two or more settings (e.g., at home, school, or work; with friends or relatives; in other activities). The following conditions are listed on the CDC's Web page on symptoms and diagnosis of ADHD (CDC, n.p.).

- Several inattentive or hyperactive/impulsive symptoms were present before age 12 years.
- Several symptoms are present in two or more settings (e.g., at home, school, or work; with friends or relatives; in other activities).
- There is clear evidence that the symptoms interfere with, or reduce the quality of, social, school, or work functioning.
- The symptoms do not happen only during the course of schizophrenia or other psychotic disorder. The symptoms are not better explained by another mental disorder (e.g., mood disorder, anxiety disorder, dissociative disorder, or a personality disorder).

Diagnosing ADHD is a process. No single test or scan identifies ADHD. Symptom behaviors

occur in many settings, so input from family and other caregivers provides valuable information based on their deep knowledge of the child. Caregivers may use checklists to record data of behaviors that are cause for concern. For a diagnosis that captures the range of behaviors across settings over time, it is important to get information from each caregiver about the child and his or her ADHD symptoms. Research by Megan Narad and colleagues indicates that the correlations between parent and teacher ratings of ADHD behaviors are only weak (inattention) to moderate (hyperactivity/impulsivity).

The prevention of challenging behaviors associated with hyperactivity and impulsivity are concerns for parents, caregivers, and teachers, but all preschool children at one time or another demonstrate hyperactivity, aggression, and oppositional behavior. When these behaviors reach a significant level over time and in multiple settings, they may signal a need for specific treatment. Most children are not diagnosed with ADHD in preschool, but the evaluation and data collection that start there are useful for later diagnosis. Data collection in school or preschool should show behaviors over time across the school year and behaviors in different settings (including both home and school) and should record the success or failure of different interventions.

ADHD is a long-term disorder. It is often recognized during the preschool years, particularly when the symptoms are significant, but management of the disorder must be considered long-term from the start. The idea of something being long-term at the preschool age can be daunting. Families usually want to resolve their child's diagnosis, not manage it. Everyone working with the family must emphasize that managing the condition will likely lead to improvement in behavior and school success.

A child with ADHD does not always require special education. ADHD is not listed in the federal Individuals with Disabilities Education Act (IDEA) as one of the 13 disability categories under which 3- through 21-year-olds may be eligible for services. For eligibility in a category of special education, there must be documentation of an educational need for services. A child demonstrating an

academic or behavioral need is one who struggles academically or does not successfully function in the group—perhaps engaging in disruptive behaviors.

Children with an ADHD diagnosis may also exhibit characteristics associated with a specific learning disability. If the child has a specific learning disability, he or she would be eligible for special education services under IDEA. Children with ADHD may also qualify for services under the IDEA within the category of “other health impaired.” A child who is academically successful, but whose function in the classroom is otherwise impaired, may receive educational services under Section 504 of the Federal Rehabilitation Act, which provides accommodations and adaptations to help students with ADHD in the general education setting.

Management of ADHD usually falls into two categories: behavioral interventions and medication. The 2011 clinical guidelines created by the American Academy of Pediatrics prescribe specific actions for clinical practitioners to follow when evaluating and treating ADHD. The guidelines call for evaluation of ADHD to begin at age 4. Diagnosis should carefully follow the DSM-5, including documenting the observation of symptoms in multiple settings. Reports from parents and/or other primary caregivers should be included in the data. Evaluation should also include assessment of other possible co-occurring conditions, including developmental disorders, emotional and behavior conditions, and physical disabilities. The key recommendation from the 2011 guidelines is that the first line of treatment should be only behavioral intervention but that medication can be added if the behavioral treatment alone is insufficient.

Behavioral Intervention

Prevention of challenging behavior can be effective. Once a child establishes a pattern of disruptive behavior, it is difficult to change. A combination of evidence-based strategies to prevent and intervene often leads to lasting effects. A good start is to teach all children the skills they need in the classroom or group setting. Teaching

children emotion vocabulary and expected social skills, as outlined by the Center on the Social and Emotional Foundation for Early Learning (CSEFEL), can enable success for children in social interactions.

K. S. Blair and colleagues report ways parents as well as teachers can create routines at home for difficult transitions such as bedtime, naptime, or meals. Classroom teachers can also create routines for lining up, taking turns, and going in and out of groups in ways that are developmentally appropriate. When a teacher or parent sets clear limits, children learn to follow rules and to manage their behaviors. All children need boundaries, but children with ADHD may need more reinforcement of those boundaries. Establishing a supportive environment with clear expectations has been shown to decrease disruptive behavior.

Although behavioral strategies help to shape behavior and function for a child with ADHD, they do not cure or intervene with the core cause of the condition.

Parent–Child Intervention

Defined parent training is the first strategy recommended for families of young children who are at high risk for, or have been diagnosed with, ADHD. Parent–child intervention therapy is a systematic approach to help family members learn to shape their child’s behavior. It usually begins with strategies to increase the responsiveness of the parent to the child. Early child and mental health researchers at the Society for Research and Child Development, along with Perry Butterfield and colleagues, and Lise Fox and colleagues support the development of the responsive relationship as it is shown to develop a good foundation that allows good follow-through with behavioral interventions later.

Attachment theory is based on the idea that a warm, sensitive relationship helps secure attachment and also provides a strong foundation for children to function effectively. Amanda Williford and Terri Shelton identify that a major component of parent–child intervention therapy is for parents to practice behavior modification strategies at

home. The Incredible Years Training Program, a psychosocial approach to supporting parent–child relationships, is another example of a well-supported parent intervention program for children with ADHD and their families.

Teacher Intervention

Children who exhibit challenging behaviors associated with the hyperactive/impulsive presentation of ADHD tend to have difficulty forming close relationships with teachers and peers. They tend to be less engaged in learning activities. Fortunately, there are many well-established evidence-based strategies for prevention and intervention with children who display disruptive behaviors. Fox and colleagues suggest a sequence of prevention and intervention strategies grounded in applied behavioral analysis and focused on identifying the antecedents and consequences of the behavior. According to Maureen Conroy and colleagues, behavioral principles based on applied behavior analysis theory are characterized by setting an environment that provides a fine balance of structure and boundaries with sensitivity to recognize subtle behavior changes. Children diagnosed with ADHD tend to lack the self-regulation skills needed to complete a task. These skills are referred to as executive function skills. The classroom practices that follow can assist children with ADHD, by both diminishing challenging behaviors and improving executive function skills:

- Clear behavioral expectations in the classroom; e.g., teach children explicitly what to do during each learning center activity.
- Natural consequences that are reinforcing when complete; e.g., by promptly responding to a call for getting jackets on, outdoor play time is maximized.
- Time limits for each step of a task; e.g., use a timer to indicate how much time is available to put shoes on after a rest period.
- Visual pictures or icons to represent a single task or the events of the day; e.g., visual schedules can help a child complete a task like hand washing by showing pictures of all steps of the

task. The Technical Assistance Center on Social Emotional Intervention has organized evidence-based materials such as visual prompts for early childhood teachers to use in classrooms.

Pharmacological Therapy

According to the American Academy of Pediatrics 2011 clinical guidelines, although behavioral intervention should precede medication, when it is not sufficient, medication should be considered. Medications for ADHD fall into two categories: nonstimulants and stimulants.

Stimulants are the most commonly prescribed medication for ADHD, and between 70% and 80% of children with ADHD respond well to these drugs. Children report increased attention, fewer distractions, and better focus when taking the drugs. The two most common types of stimulants are methylphenidate and amphetamines. Although it seems contradictory that stimulants increase attention, animal and human subject research has consistently shown that stimulants increase alertness and energy.

The Children and Adults with Hyperactivity Attention Deficit Order (CHADD) website outlines the benefits of stimulants for individuals with ADHD. The stimulants work quickly and effectively for most children. Elizabeth McClain and Erin Jewell Burks write that stimulant medications sometimes generate side effects. The most common side effects include appetite reduction, weight loss, sleep disturbance, headaches, and stomach pain. Growth delay is another concern; however, research findings indicate that growth delays end after about 6 months of medication, and normal growth rates return. Preschool teachers must carefully monitor young children taking stimulant medication.

Nonstimulants were approved by the U.S. Food and Drug Administration for treating ADHD in 2003. They are usually prescribed when stimulant medications are either ineffective at relieving symptoms or are causing side effects. McClain and Burks identify three commonly prescribed nonstimulants: atomoxetine (brand name: Strattera), clonidine hydrochloride (brand name: Kapvay), and guanfacine extended-release (brand name:

Intuniv). These medications have been found to decrease distractibility and impulsivity and increase working memory. Negative aspects of these drugs are that they may affect the child's mood and may not change behaviors until the child has been taking the drug for several weeks.

ATYPICAL DEVELOPMENT

Atypical development refers to situations in which children's behaviors vary from normal expectations. The behaviors might vary in the timing of their appearance (e.g., late in speaking), in the sequence of their appearance (e.g., walking before crawling), or in their form (e.g., perseverative play with one toy or object). These instances of atypical development can occur in one or more areas of a child's development: physical, sensory, cognitive, language, or social-emotional.

It is important to note that diversity is expected in normally developing children, both between individuals and within a given child. For example, some children may be stronger in language than in physical skills and one child may have advanced cognitive skills but less well-developed social interaction skills. There is a wide range of normal timing for achieving most developmental milestones (first steps, first words, etc.). Development is only considered atypical when it doesn't fit into normal ranges on developmental charts and inventories and/or is considered outside the range of normal in the judgment of a professional evaluator.

Children's development may depart from the norm for a variety of reasons. They may have disabilities that are genetic or chromosomal in origin, for example, Down syndrome. There may have been medical difficulties before or during birth. They may be negatively influenced by a variety of environmental factors that impinge upon their development, such as environmental toxins, inadequate nutrition, or lack of appropriate stimulation and nurturance. In some instances of atypical development, causation is complex and not yet clearly understood. The term *atypical development* is frequently used by professionals to describe developmental variations for which there is no other specific diagnosis, for example, autism or cerebral palsy. Although gifted children, who often achieve developmental milestones significantly ahead of the normal range, could be considered to show atypical development, this entry focuses on atypical development that is deleterious for young children's development. The entry discusses cautions in identifying atypical development

and explains how atypical development is identified. It then discusses why early intervention can be important in cases of atypical development and the types of services and interventions available.

Cautions in Identifying Atypical Development

Often caregivers and early childhood teachers are the first to notice atypical behaviors in young children. Their training and experience makes them valuable in observing children's development and in seeking corroborating information from other professionals and from families. However, young children are sometimes inappropriately labeled as exhibiting atypical behavior. This is more likely to occur in situations in which children engage in disruptive behaviors, where their culture differs from that which is predominate in their environment, and when their family's primary language is not English.

Cultural Considerations

Children's family and cultural environments can influence their behaviors and even their performance on developmental scales. Children for whom English is a second language may not understand the instructional language and varied conversations that occur, especially in group settings. In such cases adults might incorrectly perceive them as slow learners, noncompliant, lacking in initiative, or asocial. In addition, normal cultural expectations may present problems. For example in some cultures, eye contact with adults is seen as disrespect. Yet at school a child might be considered inattentive or be reprimanded for not making eye contact with the teacher or caregiver.

Teachers and caregivers are influenced by culture too. Researchers found that when early childhood caregivers from two different cultures were asked to rate the importance of a variety of skills and competencies for children up to age 6, their answers were significantly different and reflected their own cultures. It seems that a caregiver's own cultural background is likely to influence his or her perceptions of atypical behaviors as

well as determine the strategies used in working with children. Clearly any assessment to determine if a child's development is truly atypical must involve a range of family and environmental considerations.

Setting Considerations

Children's misbehavior in group settings (child care, preschool) frequently leads to their being singled out as having developmental problems. It is important to remember, though, that young, normally developing children are still learning behaviors such as self-control, attention, flexibility, empathy, and compliance. Children who have no siblings or playmates at home, for example, might need more time to learn interaction skills than children from other families. Children's personalities differ as well; some are more active than others, some quieter than others. Yet some group settings are relatively inflexible in meeting the diverse needs of these young learners. Finally in some cases the group setting itself supports a child's misbehavior, especially if staff regularly pay attention to (correct or punish) the child's disruptive behaviors with little nurturing and supporting of positive behaviors. Careful, systematic observation is needed to determine if children's behavior is reflecting true disabilities or if there are other explanations.

Identifying Atypical Development

Atypical development can be observed as early as infancy, for example, when an infant's responsiveness to environmental stimuli is significantly less or greater than expected. However, it might not be evidenced until children are in preschool or as late as the early elementary grades. Many children with learning disabilities are not identified until the elementary grades. Whatever the case, it is important to assess the child's situation as soon as concern is raised and to provide intervention where needed. Early intervention is critical and often can prevent secondary disabilities from occurring.

To accurately identify a child as exhibiting atypical development then, a thorough assessment must be conducted. Any authentic and comprehensive assessment of young children should be culturally

sensitive, involve information from multiple sources, and reflect the varied settings in which the child participates (home, school, play, etc.). Effective assessment techniques include developmental screening using standardized tools such as developmental checklists, rating scales (e.g., the Bayley Scales of Infant and Toddler Development), professionally conducted systematic observations of the child in a range of interactions and settings, and family input through use of checklists, observations, and interviews.

The outcome of this systematic assessment is to describe a child's achievement of developmental milestones, unique developmental patterns, and functional abilities, and to ascertain whether the child's developmental variations reflect a true instance of *atypical* development rather than normally occurring differences in development. If the conclusion is that of atypical development, it is important that the assessment identify appropriate strategies for supporting and monitoring the child's continued developmental growth. This evaluation can then provide guidelines for early intervention tailored to the child's unique situation.

Authentic assessments should include information about a child's strengths as well as needs. Successful interventions nurture children's learning through engaging their interests and abilities. Assessments should also include information about the child's family and environmental situations (home, school, neighborhood) that may be supportive or may put the child at further risk developmentally. For example, a parent who is attentive and who interacts and talks with a young child regularly is providing a support that is lacking in situations where a parent is stressed and seldom focuses on the child. The strengths, interests, and needs of the child's family and environment are important factors in developing successful intervention programs. In situations where there is need for more effective nurturance and responsiveness in the child's environment, early intervention can support the roles of families and caregivers, making them more effective in facilitating their child's development. A program that is responsive to the needs, abilities, interests, and dispositions of the

family as well as those of the child can help establish a resiliency that enables the child to continue growth on an appropriate developmental path.

Early Intervention

Need for Early Intervention

Early intervention is important for all children who are identified as exhibiting atypical development, even in cases where the behavioral differences noted are mild. It is very difficult to determine between children whose atypical development will likely be temporary and children whose difficulties will persist and be pervasive. Too often families are advised to wait and see if a child's behaviors will improve over time; when this happens, the child, family, and caregivers miss the valuable support that could enhance the child's learning and prevent further developmental problems. Children who have difficulty communicating will miss out on numerous opportunities to learn language and to socialize. Children who have difficulty interacting with others will miss opportunities to explore the environment and to build social relationships with adults as well as peers. Situations such as these hinder a child's ability to learn through normal everyday experiences. Sometimes a year or two of early intervention is all that is needed for a child to acquire new abilities and continue to progress on a normal developmental path, preventing the future development of any learning or behavioral disability. Certainly in cases where a child's developmental deviations are enduring, early intervention is of critical importance.

Services and Interventions

Intervention can provide families and caregivers with information to understand and accommodate to their children's difficulties. It can identify helpful community resources, strategies for dealing with difficult situations, and successful, positive approaches and techniques for nurturing children's learning. Goals for the intervention services are based on the assessment information and incorporate the strengths and needs of the child, family, and learning environment. The services and support

provided are typically delivered through home-based and/or center-based programs (agencies, child care, preschool, school). It is important, however, that the intervention efforts include children's families, regardless of the program location. Supportive families are necessary as children transition from one program to another and face new developmental challenges. They are needed to provide important teaching and support throughout a child's life.

Depending on the child's developmental concerns, intervention may involve a variety of professionals, such as early learning specialists, special educators, physical and occupational therapists, speech and language specialists, psychologists and child behavior specialists, social workers, and medical personnel. An IFSP (individualized family service plan) or IEP (individualized education plan) will be developed based on assessment findings as well as input from the child's family, caregivers, teachers, and involved professionals. The plan will identify appropriate goals for the child, state the services and educational techniques required to achieve those goals, and establish a method for evaluating the progress toward those goals.

Families and professionals will continue to meet regularly to ensure that the educational plan is effective and to make changes where needed.

Early intervention programs provide important resources for young children identified as having atypical development, and also for their families and caregivers. When these efforts are in place early in a child's life, they enhance children's learning and development. They can modify obstacles to a child's normal developmental progress by encouraging behaviors such as attentiveness, self-control, and positive interactions with peers. They further enhance children's resiliency by supporting effective parenting and caregiving.

AUTHENTIC ASSESSMENT

As children mature, they often develop unevenly across developmental domains. Reliable studies also confirm wide variations among children of the same chronological age relative to changes in physical, cognitive, social-emotional, and aesthetic development. These facts alone render single, more conventional assessments less useful or reliable in documenting what children actually know and can do at any particular age. This is the most compelling reason why increasing numbers of educators in the 1980s began to question the efficacy of traditional methods of testing (e.g., paper and pencil tests) and to call for more practical alternatives. Early advocates such as Grant Wiggins, P. David Pearson, Elfrieda Hiebert, and others began to press for the use of what they termed *authentic assessment* to measure and evaluate growth.

Authentic assessment (otherwise referred to as *performance assessment* or *direct assessment*) requires children to demonstrate fundamental knowledge or skills they have learned in order to complete real-world tasks they are given. It is effective in education settings of all types and at all levels and has proven to be a more valid procedure than relying on alternatives such as multiple-choice, paper and pencil tasks that require the learner to simply identify a correct answer. This is especially true in early childhood education where children have immature language and literacy skills, as well as limited ability to follow directions or interpret printed instructions. Also, because young children have little understanding about the importance of assessment or interest in doing well with traditional modes, creative and interesting authentic assessment tasks are more likely to arouse their interest and maintain their attention.

Although the aim of both traditional and authentic assessment is to measure attainment of essential knowledge and abilities, authentic assessment goes a critical step further in that it requires *demonstration* of the knowledge or ability. The student must be able to actually *do* something with the acquired knowledge or skill. Thus, the two methods of

assessment look quite different in practice. This entry discusses characteristics of authentic assessment and important ways in which it differs from more traditional assessment, a variety of effective outcome measures, and commonly used strategies that can be used to evaluate students' products, demonstrations, and performances.

Characteristics of Authentic Assessment

In 2003, the National Association for the Education of Young Children (NAEYC) and the National Association of Early Childhood Specialists in State Departments of Education (NAECS/SDE) issued a joint position statement about what they believe constitutes ethical, appropriate, valid, and reliable assessment for children, birth through the primary grades. They acknowledge that individually administered norm-referenced tests may be needed to make sound decisions about children requiring early intervention; however, they caution that these should be limited in general practice and should always be accompanied by corresponding evidence.

There is widespread agreement in the field of early childhood education that in order to be considered *authentic*, assessment must be guided by ethical practices and conducted in concert with the following considerations:

Methods used are developmentally appropriate. The assessments that are selected take disabilities into consideration and are age appropriate, individually appropriate, and culturally and linguistically appropriate. Whenever normed measures are used with children who are English language learners (ELLs), non-English proficient (NEP), or limited-English proficient (LEP), the validity of passing scores and cutoffs is a critical factor. Because proficiency in a second language progresses in distinct stages, functionality in academic language takes far longer than that of conversational language; as a result, conventional measures can be strikingly inappropriate for these students. A child may actually know the answer to a question posed but

cannot read or understand the question well enough to select the correct response. Frequently, workbooks and worksheets fall into this category.

The tasks that are created should flow from a set of content standards or listings of what educators believe children should know and be able to do. According to psychology professor Jon Mueller, author of *The Authentic Assessment Toolbox*, standards should always be written so that they are amenable to assessment. Because standards are somewhat broader than objectives, the tasks that spring from standards may typically involve more time, more than a single topic, and even more than one discipline. Consider the task given to small groups of second graders to work together to create a papier-mâché globe showing the continents and bodies of water they have studied. The teacher moves among the students, observing carefully and documenting many aspects of what has been taught and learned. She notes such evidence as what each child can do independently; ability to follow directions; use of the materials; attention to task; ability to spell correctly the names of the continents and bodies of water; the use of art and math abilities in determining shape, proportion, and proximity of land and water; ability to work collaboratively with others; use of the computer to create printed labels; and use of the Internet to access further information to create what they want. This is an example of a deep and broad activity that yields not only information about the students' geographic understandings but also evidence about their abilities to draw on other critical aspects of learning.

Materials and tasks selected for authentic assessment should be based on children's interests and abilities, with continuous reflection about children's current achievement levels. When assessments are designed by companies or organizations that have no idea about the specific standards created for the students being evaluated, they can rarely be considered authentic.

All developmental domains are evaluated, not just academic productivity. A lack of maturity in fine

motor skills, cognitive processing, self-regulation, emotional development, and socialization can significantly and negatively influence children's ability to learn or effectively apply what they are learning. They, too, should be evaluated.

Classroom teachers are trained in ways to creatively coordinate content standards with instruction and design valid, reliable, and efficient ways to measure and evaluate children's progress or lack of attainment. They are knowledgeable about standards related to what they should be teaching, about how children learn and develop, and about the importance of providing adequate time and opportunities to support learning prior to assessment.

Assessments are tied to children's daily activities and conducted in the natural learning context by persons familiar to the child. To produce the most accurate results, data are routinely gathered from realistic settings and situations reflecting what children know and are able to do.

Assessments conducted are purposeful, beneficial, educationally significant, and bridged in a thoughtful and careful manner to published standards. Students' responses contribute in a meaningful way to adjusting instructional planning, advancing program development, identifying any special needs, and moving children's learning forward.

Assessments are designed so that the tasks themselves are authentic; that is, they are closely aligned with what students will have to do in real life. This is what establishes a task's validity, which is a critical technical requirement of any type of assessment. The reliability of assessments results from standardizing criteria for evaluating the quality of students' responses, usually in the form of clarity-producing rubrics or exemplars that are shared with learners during the instruction phase and prior to assessment. The tasks given require a deeper understanding by calling for some sort of application, analysis, or synthesis on the part of the student.

Multiple sources and reasonable amounts of evidence are gathered periodically over time and used for planning and decision making, keeping in mind the following:

- There must be a sufficient *variety* of measures offered so that children have choices in how to demonstrate what they know. In some cases, students themselves may also be encouraged to create valid and legitimate applications of some sort to show proficiency.
- The assessment tasks that are created allow for individual variation in the children being tested and take into consideration differences in styles and rates of learning. For example, according to Scott Barry Kaufman, scientific director of the Imagination Institute at the University of Pennsylvania, children who have been diagnosed as having attention-deficit/hyperactivity disorder (ADHD) have different neural networks. While a classmate with well-developed executive function may score exceptionally well on conventional tasks, a child with ADHD probably will not; however, he or she may function quite well—and even better—on applied tasks that require creativity, imagination, or out-of-the-box thinking if given an opportunity to display ingenuity. Innovative people who were considered early misfits in the classroom, such as Thomas Edison, Winston Churchill, Albert Einstein, Steve Jobs, and Michael Faraday, likely would have benefited from such an approach.
- There should be multiple data points collected, and outcomes from one test should never be used to make decisions about educational placement or aptitude. Traditional assessments, often called “snapshots in time,” cannot capture the dramatic kinds of changes in learning that take place from day to day, sometimes overnight in many young learners.
- Traditional measures, which are summative rather than formative in nature, rarely contribute to a teacher’s ability to make needed adjustments to instruction in a timely or meaningful way.

Principled data gathering is a shared responsibility among teachers, children, administrators, parents,

and others concerned with the child’s ongoing development and well-being. This requires effective communication among these participants. Educators who decide to use normed or criterion-referenced tests should be informed about whether there are sufficient validity and reliability for a particular test, whether the norming group is representative of the children to be tested, how to interpret statistical meaning of derived scores, and how to share the information in a useful way with all stakeholders. When using end-of-the-unit traditional assessments, teachers should first assess the quality of instruction they have provided to the learner and whether or not the items are truly representative of what children should know and be able to do. Children should be involved in keeping track of their own progress and encouraged to set their own goals for further learning and skill development.

It’s clear that many of the principles of authentic assessment just mentioned can be routinely violated when educators rely too heavily on conventional methods such as paper and pencil tests to document how children are progressing in their learning. The following section gives a sampling of alternative strategies that educators may use in keeping with the principles of authentic assessment.

Strategies for Authentic Assessment

Because authentic assessment requires students to apply knowledge and/or skills, measurable outcomes usually fall into three major categories: products, demonstrations, or performances.

Products

Products result from any number of tasks carried out in the regular learning context and are specifically related to what children have to do with the skills and concepts under study. The products could consist of the following:

- Artwork
- Musical compositions
- Many types of written and illustrated materials (e.g., advertisements, letters, poems, journals,

science logs, surveys and tallies, graphs, maps, written book reviews, reports, graphic organizers, newspaper articles, posters, nursery rhyme repetitions)

- Pictures of constructions, documentation boards, and other artifacts from project work
- CDs that demonstrate reading progress from grade to grade
- Videos of performances, podcasts, slide presentations, and photos with narratives

Anything that children can produce while drawing on the academic skills and knowledge they are acquiring is a legitimate product—the more creative and enterprising, the better.

Keeping Track of and Organizing Products: The Use of Portfolios

Portfolios are rich, purposeful, and dynamic hard copy or digital collections of students' products over time. The contents are unique to each child and provide tangible evidence of academic growth and achievement, showing a child's best work from selected domains and at particular points in time. Because they are shared periodically with others, such as during student-led conferences, portfolios foster pride in students, causing them to be reflective evaluators of their own work and strengthening the connection between home and school. As students learn how to organize and maintain these collections and share the contents with their classmates, teachers, parents, and others, they are in fact learning other important life skills about communication, self-appraisal, goal setting, and their own learning trajectory.

Demonstrations

Demonstrations are constructed responses from students that usually directly follow a teacher prompt to show acquisition of particular knowledge, skills, or both. Examples of authentic demonstrations include the following:

- After studying electrical circuits and then constructing one of their own, students are asked to then demonstrate and explain to a classmate,

the teacher, or to another classroom of students how their circuit works.

- Children are asked to demonstrate automaticity with addition (or subtraction, multiplication, and division as appropriate) by solving as many given problems as possible in a 5-minute time period.
- To see if reading is on a grade level relative to accuracy and comprehension, the teacher administers reading inventories periodically to individual children.
- Dyads of prekindergarten children who have been studying geometric shapes are given a number of small paper squares, circles, rectangles, and triangles. They are asked to attach them to objects or places where they discover the various geometric shapes in a walk around their classroom and then around the school.
- After studying characteristics of leaves, students enjoy a field trip to a local arboretum where they find, draw, and label in their science journals at least five different kinds of leaves.
- Students in a mixed third- and fourth-grade classroom have been learning about differences in literary genre. Teachers Charles Nicholas and Katherine Crawford provide small groups of students with a variety of grade-level books from the school library. The students are to review as many books as possible and complete a form that obliges them to differentiate between nonfiction (also telling whether it is a biography, an autobiography, or informational) and fiction (telling whether it is historical, realistic, science, a mystery, or a fantasy).

Child Self-Assessment

When we talk about authenticity in assessment and evaluation, a key component is making sure that children are drawn into the process so they have ownership and investment in their own learning and progress. An example of a self-appraisal exercise can be seen in Figure 1 where 4-year-olds have been asked to complete an "I Can Do Math" self-assessment. The teacher has created a checklist of skills drawn from the school's math standards and the many math-directed activities the children

Figure 1 Self-Appraisal Exercise

I CAN DO MATH

PreK–Level 2 Self-Appraisal

Directions: Observe and have child color in or check box if he/she has been able to demonstrate the skill. Use appropriate concrete materials for tasks. If child completes all skills prior to the next assessment period, create a new list of skills to evaluate additional math abilities.

Child's Name: _____

SKILL/DATE	October	February	May
I CAN:			
count to 20 in stable order.			
demonstrate 1–1 correspondence up to 10.			
write numerals 0–10.			
read a number line through 20.			
say ordinal numbers to 10.			
create and extend a pattern.			
order a set of materials by height or width.			
measure length, using a nonstandard measure.			
compare sets to 10, telling more than, less than, the same as.			
create a circle, square, triangle, and rectangle.			
add numbers within 5.			
subtract numbers within 5.			
pose a question and collect data.			
display data with assistance.			

What skill will you work on for next time (describe/date)? _____

Date: _____

have experienced from the beginning of the school year. As the teacher reads a skill on the list (e.g., count to 20 in stable order), the child demonstrates the skill. If successful, the child checks or colors in the box indicated; if not yet able to demonstrate the skill, it is left blank with the teacher saying, “This is one for us to keep working on.” This keeps the targeted skills in the teacher’s mind relative to subsequent instruction and also maintains the child’s focus about what still needs practice.

Dynamic Assessment

Brief mini-conferences, which involve teachers interacting with an individual child or a small group of children, allow teachers to gain information about what students understand and can apply. For example, a kindergarten teacher is trying to determine a child’s level of comprehension about a story that has been read to him. The child has limited English skills and is not yet able to communicate expressively in English, although his receptive

English language is clearly growing. Using a series of cards with pictures sequencing the story line, the teacher asks the child to line them up according to the way the story happened. When the child does so, quickly and confidently, the teacher is satisfied that the child's receptive language, attention during shared reading experiences, and concepts about literature are developing satisfactorily.

Performances

Performances can be considered the gold standard for authentic assessment. As defined by Jon Mueller, they are usually broader than a constructed response or demonstration, are more substantial in depth, and require more time to complete. Included could be sports competitions, musical concerts or dance performances, readers' theater, plays, authors' nights, debates, skits, and many other real-life applications of learning. They can result from a teacher prompt or spring naturally as a culminating experience at the end of a theme or project. Examples include the following:

A fifth-grade class wants to find a way to contribute to a local charity. The students decide that for one week, they will open and operate a school store where students and parents can purchase some appealing products. The profits will be given to the charity. The students prepare a slide presentation for administrators of the school, requesting funding for the products they need to purchase and which they believe they can make a profit on. They include a rationale for the store; how it can benefit them as learners; a list of products and where to get them; a budget; a timeline for implementation of the project; and a plan for students' responsibility in set-up, before- and after-school sales, and take-down. Receiving the funding, the students work together to implement the project; deliver the profits to the local charity; and hold a meeting with administrators to return funding, thank them for their loan, and report on the academic and personal value of the project.

Second graders in an international school in Beijing, China, have prepared an original poem, which they have written in both Chinese and

English. The teacher arranges for friends and family members to come in to listen to a reading of the poems in both Mandarin and English by the students.

Kindergarten students have been involved in a semester-long theme about fish. They have obtained pictures of different kinds of freshwater and saltwater fish from information books and the Internet, have learned the names of them, have replicated them during their art period, and have dissected a large fish. Following a field trip to the local aquarium where they went on a "fish hunt" to find a certain specimen, they have created an underwater mural along two walls of the classroom and have invited family members and other classes to come in to see the "aquarium." These young ichthyologists are able to tell their visitors the names and colors of each fish, what they eat, how a swim bladder allows them to rise or descend in the water, and what happens if the water becomes too dirty.

Evaluating Task Performance

For evaluation of tasks in any of the three categories just described, rating scales or rubrics are extremely useful. Rating scales are similar to teacher-constructed checklists in that variables of interest are listed; however, there is always an *evaluative* component with rating scales that defines a categorical range of behavior/skill acquisition (e.g., skill is well developed, skill is practiced often but not always, skill is rarely observed). Variables can be represented along a numbered criterion (0–10, in which 0 = low and 10 = high) or an open continuum of extremes or opposites (e.g., incomplete to complete, control versus autonomy, self to other). Subjectivity in making a decision about where to place or "grade" a student along a continuum or placement in a particular category can be a problem if there is bias and requires caution on the part of the rater.

Rubrics are somewhat more objective. Instead of a simple rating of a trait or behavior, there are two or three qualifying criteria that must be observable and must be met. These should be clear and distinct. For example, students may be given

Figure 2 Student-Led Conference Rubric

Criterion/Score	5	3	1
Selection	I was able to explain to my family why I selected the pieces that I included. There was at least one selection from all of my subject areas.	What I said was okay but would have been better if I had practiced a little more. I included samples from most of my subject areas but not all.	I couldn't explain why I selected the pieces. There weren't any samples from one of my subject areas.
Organization	I organized my portfolio well. It was easy to find what I wanted to show to my family.	I needed too much time to look for the different subject areas but almost everything was there.	My portfolio was disorganized. I couldn't find some of my best work.
Participation	I loved showing my family how much I have learned. It was fun.	I liked doing this. I'll like it better next time when I'm better organized.	I wasn't ready for the conference at all. I didn't work hard enough to get ready.

a rubric ahead of their student-led conference that helps them understand the kind of application the teacher expects and desires (see Figure 2). These serve as a guide for the conferences, and children also use the rubric in a debriefing discussion following the conferences to self-evaluate their performance. Learning to use a rubric as a self-appraisal tool contributes significantly to children's expanding independence and ability to take responsibility for their own learning.

Authentic assessment offers educators ethical, valid, and reliable strategies for finding out if what they are teaching is really working. Students who participate in authentic assessment become equipped with the knowledge and skills that will benefit them throughout their lives, including self-reflection, critical thinking, organizational skills, and an ability to communicate and collaborate well with others.

AUTISM SPECTRUM DISORDER

Autism spectrum disorder (ASD) refers to an array of neurodevelopmental disabilities that are typically expressed as difficulties in social, communication, and emotional learning and behaviors. Though the term *autism* has been in use for nearly a century, the incidence of this disorder has been rising regularly. In 2014, the Centers for Disease Control and Prevention estimated that 1 in 68 children in the United States has been identified as having ASD, with the incidence among boys almost five times that of girls. There is great diversity in how this disorder appears in children; hence, it is described as a spectrum of behaviors. It varies in timing of onset (though it emerges in the early years), the behavior challenges exhibited, and the severity and pervasiveness of those challenges. This entry presents a discussion of child behaviors commonly associated with ASD, the diagnosis and classification of ASD as a disability, the services and types of intervention available for persons with ASD, and the prognosis for those with ASD.

Behaviors Associated With Autism Spectrum Disorder

Autism spectrum disorder can be identified as early as infancy, but most often it is diagnosed by the second or third birthday. When children's symptoms are milder, it might not be identified until they begin school or later. Diagnosis is done by professionals who interview parents and teachers and perform behavioral observations and assessments. Children with ASD experience challenges in social, communication, and emotional development. For example, they might avoid interaction with others, not make eye contact, not initiate or respond appropriately to social interactions, not react to others' feelings, be extremely noncompliant, or become easily upset by changes in routines. Their language may be delayed or have stereotypic characteristics such as being repetitive, echolalic, excessively literal, lacking in emotion, or having unusual prosody (intonation and rhythm). They might engage in repetitive

motions (rocking, hand flapping), display obsessive behaviors (showing interest primarily in one toy or topic), or have unusual sensitivity to environmental stimuli. They have difficulties in understanding and engaging in social reciprocity and may find it difficult to form relationships with others. Intellectual disabilities may or may not be present. Sometimes unusual talents and abilities are present, for example, being able to focus on a topic or problem for extended periods of time.

Diagnosis and Classifications of Autism Spectrum Disorder

The American Psychiatric Association develops and publishes guidelines for diagnosing an array of mental disorders. These guidelines, known as *The Diagnostic and Statistical Manual of Mental Disorders* (DSM), are used by a range of clinicians and are relied on for determining the necessity for and funding of therapeutic services. In the fifth edition of the manual (DSM-5), released in 2013, the American Psychiatric Association narrowed its definition of ASD. However, because in some places the former diagnostic classifications remain in use, both are described here. The former diagnostic classifications are discussed first, followed by an overview of the more recent description of ASD in DSM-5.

Former Diagnostic Classifications

Until recently ASD was described as having three classifications: classic autism, Asperger's syndrome, and pervasive developmental disorder—not otherwise specified (PDD-NOS). These three classifications reflect variations in how ASD is expressed in individuals, such as the severity of symptoms and its pervasiveness across developmental areas.

Classic autism refers to individuals with the most serious symptoms. These children communicate very little if at all, may engage in repetitive and stereotypic motor behavior, are very delayed in social and emotional development, have great difficulty in adjusting to environmental changes, and often have accompanying intellectual deficits.

Asperger's syndrome refers to individuals with less severe symptoms and whose symptoms are not as wide-ranging as in classic autism. For example, they typically do not have intellectual deficits and are sometimes gifted intellectually. Many of these children do not have language acquisition problems, though they typically have some communication difficulties, as in understanding another person's point of view and in understanding and expressing emotional content in language. They often have difficulty in following normal back-and-forth rules of communication.

Asperger's syndrome is often referred to as high-functioning autism, as persons so diagnosed often have remarkable abilities along with their difficulties.

PDD-NOS refers to individuals who exhibit a few but not all of the symptoms of ASD and whose symptoms are milder than those of persons with classic autism and Asperger's syndrome.

The Diagnostic and Statistical Manual of Mental Disorders Definition

The DSM-5 description of ASD differs from the three aforementioned classifications in that it omits Asperger's syndrome as a separate category, and it includes PDD-NOS as a category apart from ASD. It defines ASD as presenting difficulties in social interaction and communication. The difficulties arise in the developmental years, interfere with successful functioning, and are present across a range of situations. This new diagnostic guideline identifies three classifications under ASD based on the severity of the disability: requiring very substantial support, requiring substantial support, or requiring support.

Children previously diagnosed as having Asperger's syndrome might now be classified under ASD, under PDD-NOS if their symptoms are mild and restricted, or as having a social communication disorder if language is their primary difficulty. Although Asperger's syndrome is no longer a diagnosis sanctioned by the American Psychiatric Association, it is likely that the term will remain in use by the lay community and by persons with

high-functioning autism themselves. These individuals often identify themselves culturally as Aspergians and have support networks that are responsive to their unique needs and strengths.

Services and Intervention

Early intervention is particularly important for children with ASD. In addition to supporting children's learning, it can interrupt the development of ineffective social, motoric, interactive, and communicative behaviors. Early intervention assists parents and teachers in dealing appropriately with difficult behaviors and in interacting in ways that enhance children's development. Family physicians and parents are often the first to seek a diagnosis for a young child. Although most children are identified by the preschool years, some are not identified until elementary school. Because ASD can be incorrectly labeled as mere misbehavior, it is important to assess school-age children who appear to have social interaction problems, are noncompliant, get upset easily, or have difficulty with routines. Because children's behaviors are so diverse, intervention involves a range of settings, methods, and professionals. Medication is sometimes prescribed for concurrent conditions such as inattentiveness or hyperactivity.

Community Intervention Resources

Early intervention programs provide treatment for children from birth to age 3 and their families (in both home and center-based settings), while public school systems serve children older than age 3 and their families. These programs provide a variety of treatments and are staffed by a range of professionals. Depending on an individual child's needs, intervention might include physical therapy, occupational therapy, speech and language therapy, behavioral therapy, psychological counseling, home- or school-based education provided by an early education specialist, or inclusion in regular education programs. The services of these professionals are planned and coordinated through an individualized family service plan (IFSP) or, for school-age children, an individualized education program (IEP).

These individualized education plans identify goals for each child and describe the types of services and educational strategies to be implemented in order to reach those goals. Parents and sometimes older children are contributing members of these teams. The teams meet regularly to assess the progress and to make adjustments where needed.

Home-Based Intervention

The home setting is often most ideal for children up to 3 years of age. Home visitors meet with parents and children on a regular basis to implement the child's educational program. Educational goals focus on assisting the child and parents in managing daily routines such as eating, playing, bathing, interacting with others, talking, and dealing with disruptive behaviors. The techniques used are typically naturalistic and involve teaching through building on skills and interests already exhibited by the child, using clear and consistent language, modeling new learning, and rewarding the child's accomplishments. Because children with ASD typically present emotional challenges such as frequent refusals and tantrums, the visiting professionals can assist the parents by modeling positive ways to deal with such situations. Indeed, a clear advantage of home-based intervention is that the early childhood professionals have an opportunity to teach the parents and siblings along with the child. This opportunity to meet regularly with individual families also allows the visiting professionals to provide information and emotional support to families as they face the challenges of raising a child with ASD. When families and professionals use the same approach, the child's learning environment becomes much more consistent, enhancing the child's progress. This kind of interaction results in true family-centered intervention.

The National Autism Center has published a guide for parents to use when planning and choosing the types of intervention approaches that would best suit their children. This manual, *A Parent's Guide to Evidence-Based Practice and Autism*, presents successful, researched-based practices that range from intensive one-to-one behavioral instruction led by a board-certified

behavior analyst for children with severe ASD to naturalistic techniques such as peer tutoring that are useful in inclusive early childhood settings.

Center-Based Intervention

By the time children reach their third birthdays, intervention is typically provided in early childhood centers. Inclusion settings in which children with ASD are integrated into regular preschool and early childhood settings are quite successful for many children. Children enrolled in these settings can continue to receive regular therapy from specialized professionals, such as physical therapists, psychological therapists, and behavior therapists. Often an adult assistant joins the child in the inclusion setting to assist in negotiating the classroom, following rules and routines, and making friends with other children. Successful inclusion teachers adopt the many techniques that have been developed to support the learning of children with ASD. Examples of these are using pictures and symbols to make language more understandable and predictable, playing with children in order to establish joint attention for teaching, teaching consistent social interaction skills to all children in the class, and using scripted social stories to teach appropriate behaviors and understandings.

Prognosis

Depending on the severity of their condition, persons with ASD may need professional support throughout life. However, with early diagnosis and consistent implementation of successful educational approaches, many individuals with ASD can become competent adults and effective and contributing members of our society. Accomplished adults such as Temple Grandin and John Elder Robison have written compelling personal stories about their lives and achievements in spite of the unique challenges presented by their ASD diagnoses.

AUTONOMY

Autonomy means being self-determined, self-governed, and independent. It refers to the characteristics of being one's own person and existing and acting separately from others. An autonomous person makes choices and decisions and is able to speak for himself or herself. The opposite of autonomy is *heteronomy*, which means being governed by someone else. Autonomy does not mean complete freedom to do everything a person might want to do. Instead, it refers to the ability to be able to do things and make decisions that take into account the well-being of all concerned, including the well-being of one's self and the well-being of others. This entry provides information about the development of autonomy during early childhood and gives several theoretical perspectives on the topic. Examples of some typical behaviors exhibited by young children who are in the process of developing autonomy are also provided. These examples include representative behaviors of how young children indicate and express their desire to make their own choices and decisions regarding themselves, their wants, and their activities.

Overview

Independence and autonomy are important developmental tasks during the second year of life. The striving for autonomy and independence is based not only on the infant's social-emotional development of feelings of trust and security but also on the developmental advancements in motor and cognitive skills that occur during this period. For typically developing children, motor skills during the second year usually result in toddlers being able to walk, climb, open, close, pull, push, hold, and drop objects. Toddlers' social-emotional feelings of pride parallel these accomplishments, and they want to practice these skills. They want to do the things they see their family members and others do, which includes wanting to do more things for and by themselves. These behaviors are indications of advancements in social-emotional, cognitive, and motor development that help the child

develop a sense of autonomy and feelings of pride and self-worth. They are not behaviors that should be viewed as “misbehaviors” but rather as behaviors that indicate development is proceeding along a predictable path that leads to ever increasing motor and cognitive competence and healthy social-emotional autonomy.

Developmental Theories Related to Autonomy

The development of autonomy is a distinct stage in the theory of psychosocial development proposed by Erik Erikson. Psychosocial theory includes a series of eight universal, sequential stages of social-emotional development that occur from the beginning of life and continue throughout the human life span into late adulthood. Erikson’s theory proposes that the motivation behind human behavior is social and that the development of a sense of self results from interactions and relationships with others. According to psychosocial theory, the desire to affiliate and be with other people is the impetus behind developmental social-emotional changes that occur across the course of an individual’s life. Because the psychosocial stages are sequential, each stage builds on the social-emotional development of a person’s preceding stage or stages.

Each of the eight psychosocial stages is marked by a sense of struggle or crisis that represents different social, cognitive, and biological needs that occur over the course of the human life span. For each of the psychosocial stages there is a unique development task, crisis, or challenge that represents a turning point in social-emotional development characterized by both vulnerability and potential. Thus, the crisis that occurs at each stage has two possible outcomes, with one of the outcomes providing an opportunity for a resolution of the crisis, healthy developmental change, and increased potential. A lack of resolution of the crisis results in lack of developmental advancement and problems resolving crisis in future stages. A healthy resolution of the crisis at each stage depends on whether or not the family, other people, society, and culture meet the child’s or adult’s stage-related social-emotional needs.

According to Erikson’s theory, the development of autonomy occurs during early childhood between the ages of 1 to 3 years during late infancy and toddlerhood. It is the second stage of the theory and focuses on the social-emotional developmental crisis of autonomy versus shame and doubt. During this stage children experience the opportunity for the development of autonomy and the vulnerability of developing shame and doubt. The second stage builds on the first stage, which occurs from birth to 1 year and focuses on the development of feelings of trust and security. Having developed feelings of security and trust with their caregivers during the first year of life provides a foundation for children to begin to discover a sense of self, their own will, and that their behavior is their own during their second year. When supported by caregivers, children’s developing self-assertion and growing sense of independency potentially leads to autonomy and a positive resolution of this stage. If children are restrained too much, too restricted, or harshly criticized or punished for their self-assertion and striving independence, they may develop a sense of shame and doubt.

Learning to be autonomous requires the ability to self-regulate and to have self-control. These characteristics are important concepts in the constructivist theories of both Jean Piaget and Lev Vygotsky. Both Piaget’s and Vygotsky’s theories acknowledge the importance of self-regulation in the development of the child, but their emphasis was more on trying to understand the role of self-regulation in the learning process. Piaget’s constructivist and moral development theories stress the child’s inner cognitive development that results from direct experiences with the external world that leads to the child’s ability to make decisions that take into account the well-being of all concerned, including the well-being of one’s self as well as that of others.

Vygotsky’s sociocultural theory has significance to the idea of autonomy in that Vygotsky proposes that an individual’s attainment of autonomy requires the political commitment of the community in which a person lives. The idea of being an autonomous individual is a foundational aspect of

how a person understands himself or herself, history, culture, and society. Sociocultural theory proposes that self-regulation includes the planning, guiding, and monitoring of one's own behavior, which are components of the ability to be autonomous. Vygotsky thought that this type of development proceeded from the child's external, social, and cultural world to the inner world of the child's mind; thus, self-regulation was seen as an outcome of both social and individual processes. Self-regulation occurs as a result of the children's social interactions with others.

Vygotsky used the term *private speech* to mean speech that is directed to self. Young children talk out loud to themselves, often repeating rules of behavior and phrases they are learning from others. Vygotsky proposed that this private speech was part of the process of internalization of behaviors that eventually is transformed into inner speech. He saw private speech as the main mechanism a child uses for the internalization of social rules, social expectations, and self-regulation/self-control. According to Vygotsky's theory, private speech enables a child to monitor her or his own behavior based on the interactions the child has had with others and on what she or he has seen others do. This internalization process is the main mechanism by which children develop the ability to self-regulate their behavior.

Another theory that is related to the development of autonomy is self-determination theory. This is a theory of motivation, personality, and development that proposes that there are integrative processes that occur in human development that are relevant to learning and to a person's actions. Intrinsic motivation is an important component of self-determination theory. According to this theory, the environmental-social context can either enhance or diminish intrinsic motivation based on whether or not societal conditions support or thwart a person's need for autonomy, competence, and relatedness. Self-determination theory proposes a connection between self-motivation and self-determination with self-motivation being related to whether or not a child has opportunities to be autonomous and to make choices. Having choices allows a child to feel

that he or she has control or ownership over himself or herself and what he or she does. This process helps the child to develop a sense of responsibility and self-motivation.

Facilitating the Development of Autonomy

Based on the theories just discussed, the ways in which adults understand and respond to toddlers striving to learn how to use their bodies and minds and for independence are critical to the child's development of a sense of autonomy, self-governance, self-control, and self-worth. To facilitate children's feelings of pride and autonomy, it is important to recognize that toddlers are motivated to practice and to do what they are now developmentally capable of doing for themselves. To facilitate development, caregivers can allow toddlers to do those things for themselves that are safe and allow the child practice in making decisions and being independent. This means allowing time for the child to do things at his or her own pace and to accept the results without criticism. Toddlers often want to decide for themselves what they want to eat or what they want to do. Children begin to want to dress themselves, put on and take off their shoes and socks, flush the toilet, and wipe their own noses. Providing choices gives a child the opportunity to make decisions and to practice being autonomous. Allowing toddlers to do things they are capable of doing for themselves helps them to begin to develop self-help skills and to learn to control their muscles as well as their impulses. Being overprotective and overly critical of toddlers' attempts to do things for themselves may result in power struggles between caregivers and children as well as feelings of shame and doubt.

Learning self-control and becoming self-governed are hallmarks of autonomy and are related to the later development of moral autonomy. The guidance and teaching that young children receive during the stage of autonomy versus shame and doubt can facilitate the development of autonomy as well as the development of self-control and self-governance. Guidance strategies

that allow young children to make age-appropriate choices and allow children to do things for themselves that they are developmentally capable of doing help children to develop autonomy as well as self-control. Talking with young children about how the behavior impacts themselves and other people, including how others feel about things that occur, helps children to develop perspective taking, empathy, and an awareness of how their own behavior has consequences on others. The use of rewards and punishments with children can lead to heteronomy, overconformity or doing the “right” thing, and following socially approved rules of behavior only when an authority figure is present to monitor the child’s behavior or when a reward or punishment is likely to occur.

During the toddler period of development, young children who are striving to develop autonomy may become frustrated. There may be many things they want to do but cannot because of health, safety, and/or immature motor or cognitive development. Providing routines and helping children learn to substitute an acceptable behavior or action for one that is not acceptable helps them learn how to get their social-emotional needs met in a healthy way. Teaching young children acceptable behaviors, how to delay gratification, how to calm themselves when they are upset, and how to verbally express their feelings rather than acting them out are strategies that facilitate the development of autonomy and self-control.

Autonomy is the ability to do things for one’s own self and to make choices and decisions that take into account not only the well-being of self but also the well-being of others. Because no one theory best explains all of development, an eclectic

approach has been taken in this entry with brief summaries of several theories that are relevant to the topic of autonomy.

B

BANK STREET

With the expressed mission to improve the education of children and their teachers, Bank Street College of Education provides programs for children from infancy through adolescence as well as a host of graduate programs in education and related fields, including those leading to a master's degree in early childhood education. From the time of its inception, Bank Street has played a major role in shaping the field of early childhood education with a specialized focus on the developmental interaction approach as a way of better understanding the teaching-learning process for young children.

A Brief History of Bank Street

Bank Street was founded in 1916 as the Bureau of Educational Experiments (BEE). Its purpose was not to engage in laboratory experiments but rather to try out instructional strategies and observe their impact on children in school settings in order to better understand how children develop and learn. Drawing on the work of John Dewey, Bank Street's founder, Lucy Sprague Mitchell, and her colleague, Harriet Johnson, became a part of the child study movement that took hold in the early part of the 20th century—a movement that validated the study of children as a scientific endeavor.

Mitchell collaborated with other progressive educators, including Caroline Pratt and Elizabeth

Irwin, in establishing experimental schools in New York City and other locales where teaching practices and their impact on children could be observed firsthand. Over a number of decades, Mitchell, Johnson, and others used observational data to gain insight into the trajectory of development during the early years of life.

Their view of development was broader in scope than those of other researchers of that time. During the early 20th century, there were researchers known as experimentalists who observed children in laboratories in which their behavior was confined to that which was of interest to the observer/experimenter; others aimed to shape children's responses to stimuli into desired outcomes, giving rise to the psychological theory known as behaviorism; others were committed to psychodynamic theory and the importance of recognizing the child's inner emotional life. In contrast, Mitchell's interests went beyond physical, emotional, social, and intellectual development as discrete entities. She and Barbara Biber, a psychologist who joined BEE in 1928, wanted to achieve a deep understanding of the "whole" child—a thinking, feeling, acting being whose needs and interests must be addressed if schools are to effectively support development.

The understanding that development was not a mere process of unfolding but required an interactive engagement with the external world was prescient at a time when the theories of Jean Piaget and Lev Vygotsky had not yet arrived on

American shores. This focus on the interaction between learning and development in all its complexity is in keeping with what is known as developmental interaction, an approach not solely associated with Bank Street, but honed there over decades and applied to programs for both children and adults.

Developmental Interaction

What is developmental interaction? It is an educational process that combined research with practice long before the term *action research* appeared in the professional literature on teacher education. The research methodology employed at Bank Street and its predecessor, BEE, has always called for close observation and recording of children's behavior as they engage in the world around them.

Akin to cognitive developmental theory, the developmental interaction approach presumes that development occurs in an ordered and invariant series of stages aligned with, but not exclusively determined by, chronological age. It honors young children's role in constructing knowledge through their own active involvement in the social and physical world, drawing simultaneously on the interaction of their physical and sensory capacities, their intellect, and their inner emotional state.

In the developmental interaction approach, play is seen as the primary learning mode for young children, lending meaning to the common understanding among early childhood educators that play is children's work. Play affords opportunities to explore and experiment within a safe environment in which children can act and then observe the outcomes of their actions on the physical world and on the people around them. At times the outcomes serve to satisfy children's desires and expectations and at other times the outcomes cause disequilibrium in their current understanding of the world.

In Piagetian terms, play in its purist form occurs when children's actions on the environment are used to express their current understandings. For example, when a child puts her arms out, making motor noises and moving through space, saying

"Airplane fly," she is using her body and voice to represent her sense of what airplanes do. Her actions are satisfying in that they enable her to express her understanding in ways that are both physical and onomatopoeic.

At other times, while engaged in play activities, children may experience disequilibrium when their actions result in outcomes that challenge their existing capacities and understandings of the external world. For example, a child who first works with wooden unit blocks may construct a pile putting them one on top of the other without regard to size or shape. When the tower tumbles, the child may try again but still not immediately be able to build a sturdy tower. Over time and with persistence, he or she comes to understand the properties of this challenging material and can then engage in increasingly deliberate and effective efforts to create structures of greater complexity. For example, in a school where blocks were available to children from age 2 through age 7, a child who began working with blocks at age 2 was observed at age 7 to build a recognizable shoulder-height *Tyrannosaurus rex*.

The developmental interaction approach also aligns with Vygotsky's "zone of proximal development." This concept clarifies the teacher's role in structuring the environment to provide support to children until they are able to successfully engage in a given activity independently and also emphasizes the need for social interactions to foster children's development. In this regard, Bank Street takes children out into the world to learn about the geography and lives of the people in their communities.

Developmental interaction also explicitly affirms the deep connection between cognition and emotion. The inner lives of young children—their fears, joys, anger, motivations, curiosities—are ever-present influences in their efforts to make sense of the external world. Within the developmental interaction framework, the learning environment affords children the opportunity to engage in self-directed exploration and play, providing them with opportunities to represent their thoughts and emotions in ways that enable them to work these through in ways that enhance their development.

The indoor and outdoor spaces in early childhood settings are designed to ensure safety and promote further learning. The equipment, materials, and the daily schedule of activities offered at the beginning of the school year are based on the teacher's knowledge of the typical range of capacities of the particular age group. But even on the very first day of school, the teacher begins an ongoing process of observation in order to come to know each child as an individual with individual capacities, strengths, needs, interests, and temperamental characteristics. Through this ongoing observational process, teachers adapt the physical and social environment—the materials made available, the schedule of activities, and even the room arrangement, the interpersonal approaches to supporting and engaging each child—refining their knowledge of typical development in order to meet the needs of each individual within the context of the group.

Preparing Teachers for Developmental Interaction

How do teachers come to understand and adopt the developmental interaction approach? In 1930, the Bureau of Education moved to Bank Street in Greenwich Village, expanding its nursery school and formalizing a teacher training program that then became known as Bank Street College. Teachers who studied there were immersed in the developmental interaction approach as they worked in Bank Street's nursery, meeting regularly with Mitchell and colleagues to make sense out of their classroom experiences.

To this day, the developmental interaction approach is deliberately enacted in Bank Street's graduate programs in early childhood education. The knowledge and experience needed to employ the developmental interaction approach is covered in the breadth of courses that candidates are required to take, covering content that includes typical development, developmental variations, language development and acquisition with a focus on English language learners, observing and recording, working with families, and early

childhood curriculum with a focus on social studies as its core. In this curriculum course, graduate students go on field trips to study the neighborhood geography and inhabitants and to learn about the value of using malleable natural materials—paint, pencil, wooden blocks, sand, clay, and water—to represent what they know.

Bank Street's graduate-level instruction is also designed to stimulate candidates to explore their preexisting beliefs and feelings about children and the teaching-learning process and how these impinge on their work as teachers. Course instructors model the developmental interaction approach through in-class activities and out-of-class assignments designed to promote active learning at the adult level. Candidates construct knowledge by reflecting on and questioning what they already know and believe. Through interactions with instructors, peers, and children, as well as by reading relevant professional literature, they are empowered to build on and transform their understanding of the teaching-learning process.

All candidates seeking early childhood teacher certification have a clinical experience that is typically two semesters in duration in two or more early childhood settings. Known at Bank Street as supervised fieldwork, this experience offers additional experience with the developmental interaction approach. Each candidate works closely with an advisor who is a member of Bank Street's core faculty. The advisor observes the candidate at least once a month for approximately half a day, meets with the candidate at least twice a month, and facilitates a weekly meeting known as conference group with the group of five to seven candidates for whom each faculty advisor is responsible. The individual meetings are conducted as a dialogue about the children in the class, the classroom curriculum, and the candidate's engagement in the teaching-learning process. Individual meetings at the beginning and end of each supervised fieldwork placement include the cooperating teacher who serves as the clinical mentor to the candidate. Conference group is neither a course nor a seminar but an integral part of supervised fieldwork in which candidates share aspects of their respective

field experiences, problem solve together, and very often reveal feelings that impinge on their work in the classroom, some of which they have carried with them from their own childhoods. In this way they learn firsthand that teaching is a collaborative profession in which there are endless challenges and opportunities to develop further.

Bank Street Today

Because of its expertise in the field of early childhood education, Bank Street was invited to develop one of the model Head Start programs when this national program was launched in the 1960s. It continues to offer a Head Start program as well as an inclusive child care program, the Family Center, which serves children from 6 months to 4 years of age. Bank Street's School for Children serves children from preschool through eighth grade. The developmental interaction approach is enacted in all of these settings.

Bank Street's point of view about how to best educate young children is based on research showing how children construct knowledge through their interactions with the world. In its preparation of generations of teachers and its ongoing professional development offerings, Bank Street continues to promulgate the developmental interaction approach in early childhood classrooms throughout the United States and abroad.

BAYLEY SCALES OF INFANT AND TODDLER DEVELOPMENT

The Bayley Scales of Infant and Toddler Development are well-known and oft-used developmental assessments for children from 2 to 42 months of age. The primary use for the scales is to determine developmental delays or problems in very early development and provide information for planning interventions for children who may need it. The assessment was developed by Nancy Bayley; the third edition, in use as of 2015, is based on more than 50 years of research and development. The third edition of the Bayley Scales was published by PsychCorp (Pearson) in 2005 and is referred to as the Bayley-III. The Bayley Scales of Infant Development were first published in 1969. In 1993 the second edition was published, known as the Bayley Scales of Infant Development—Second Edition or BISD-II. Developed in the United States, all three editions have been normed and used internationally.

The Bayley Scales are individually administered assessments; examiners (the test administrators) must have specialized knowledge and training to give and interpret the results of the Bayley. The test is designed to be administered in 30 to 90 minutes, depending on the child's developmental abilities. The Bayley-III has added subscales to the earlier editions. The following subscales are available for the Bayley-III: cognitive, language, motor, social-emotional, and adaptive behavior.

The Bayley-III was developed to provide opportunity to collect data from multiple points of view.

The cognitive, motor, and language scales are administered to the child in an interactive experience by the trained examiner. Caregivers (typically parents or guardians) complete a questionnaire to provide data for the social-emotional and adaptive scales. The Bayley-III is also useful for multidisciplinary assessments because the scales can be administered separately by an assessment team.

Specific Scales

The Cognitive scale includes items that assess sensorimotor development, the child's exploration and manipulation of objects, concept formation, and memory. Types of play are a part of the cognitive assessment, for example, how the child plays with a single object, how the child uses two related objects together (e.g., putting a lid on a pan), and how toddlers and preschoolers use objects for pretend play.

The Language scale focuses on both receptive communication or what the child understands and responds to, and expressive communication, or what the child communicates to others. Preverbal communication is included, as are vocabulary, understanding of simple grammatical structures (e.g., adds an "s" to represent a plural word), and length of the child's utterances.

Both fine and gross motor behaviors are assessed as part of the Motor scale. This scale begins with such basic skills as visual tracking and object grasping and follows along to more complex movements, including locomotion, balance, and motor planning.

The Social-Emotional scale was developed by Stanley Greenspan, a pediatrician well known for his work in infant mental health. This scale includes different aspects of social-emotional development such as self-regulation, engaging others, using emotions in a purposeful manner, and using communication to solve problems.

Caregivers (most likely parents) complete the Adaptive Behavior Assessment. As happens in early development, there is some overlap between the adaptive behaviors assessed and other scales. The Adaptive scale includes assessing communication,

social behaviors, self-care behaviors (including motor behaviors), health and safety behaviors, and some pre-academics.

Administration and Interpretation

Examiners must be trained in the administration and interpretation of the scale. The Bayley-III is a standardized assessment in that it should be administered, scored, and interpreted using the standard, published protocol. A ceiling approach is used for administration; administration of the scale ends once the child has missed five items in a row. This is the ceiling of the child's performance. The ceiling approach limits the child's frustration by limiting the number of unsuccessful items administered; this also decreases the length of time for administration.

The Bayley-III is considered a normative assessment. This means that an individual child's performance on the Bayley is compared to the results of a large group of children, and the individual child's development is ranked in comparison to the group. The results of the assessment are to be used to determine the likelihood the child is exhibiting delayed or atypical development in cognitive, language, motor, social-emotional, and/or adaptive development. The data provided by the Bayley-III provides information that aligns to the requirements of the Individuals with Disabilities Education Act (IDEA) for identifying eligible infants and toddlers under Part C.

Review of the literature indicates that validity studies of the Bayley-III are still being published. A stated concern about the Bayley-III, more specifically the language and cognitive scales, is that it may under-identify children's developmental concerns because children score higher on the third edition than the second. Studies comparing scores on the second and third editions of the test have been published highlighting this concern. The BISD-II had a positive reputation for identifying children's developmental concerns; the Bayley-III has not yet equaled the reputation of its earlier edition. This does not mean the Bayley-III is not used or is not useful. Some recommendations have been made to interpret it more cautiously than the former edition.

Even with the potential concerns stated above, the Bayley Scales of Infant and Toddler Development are still a premier developmental assessment for young children and are widely viewed as an excellent tool to identify developmental concerns of infants, toddlers, and young preschoolers. Early interventionists are likely to find it useful for both identifying developmental concerns and helping families to understand their child's development.

BEHAVIOR DISORDERS

Children with behavior disorders are deemed as having an emotional disturbance (ED) by the federal Individuals with Disabilities Education Act (IDEA), which provides that children and youth with disabilities have access to a free, appropriate public education. The definition and criteria for ED are found at 34 C.F.R. § 300.8(c)(4). ED is described as a condition with

one or more of the following characteristics over a long period of time and to a marked degree that adversely affects a child's educational performance:

An inability to learn that cannot be explained by intellectual, sensory, or health factors.

An inability to build or maintain satisfactory interpersonal relationships with peers and teachers.

Inappropriate types of behavior or feelings under normal circumstances.

A general pervasive mood of unhappiness or depression.

A tendency to develop physical symptoms or fears associated with personal or school problems.

Behavior concerns often originate when a child is in a group setting such as child care or preschool. An individual child's reaction or response to a person or situation is often more easily noted as atypical when same-aged peers are in the same setting. Aggressive behavior is noted when children have opportunities to interact with peers. Biting and hitting are two such behaviors that get attention in preschool settings. In preschool settings, a child is eligible at age 3 for special educational services under the IDEA. Eligibility for special education related to behavioral concerns at preschool age (3 to 5 years) is a challenge for educators because young children are just beginning to learn about appropriate social behavior with peers. To be eligible for free appropriate public education (FAPE) as outlined in IDEA, a child must be diagnosed as fitting into 1 of 13 categories—one of which is ED.

Misalignment between diagnosis and eligibility for educational services continues to be an area of great concern for professionals working with young children as well as for the families of those children. One concern is combining emotional concerns and behavioral concerns together in one condition. Attempts to formally revise and separate emotion and behavior have been unsuccessful. Daniel Hallahan, James Kauffman, and Paige Pullen identified three common elements in the different definitions for emotional behavior disorders: (1) extreme behavior; (2) chronic, ongoing problems; and (3) violation of social cultural expectations. Although these three components are essential when defining emotional and behavioral concerns, they do not provide for a clear view across ages, especially for young children.

Confusion abounds because the diagnosis of an emotional or behavioral concern is required for eligibility for educational services, but teachers do not diagnose; school psychologists or psychologists or psychiatrists from a hospital or from a center or private practice diagnose. Diagnosis of an emotional or behavioral program for a young child is a matter for medical or mental health professionals, and the term *emotional disturbance* is not part of their labeling. Conditions such as oppositional defiant disorder (ODD), conduct disorder, obsessive compulsive disorder (OCD), and anxiety are examples of conditions associated with emotional and behavioral concerns. The manual used for assessment diagnosis, the *Diagnostic and Statistical Manual of Mental Disorders* (DSM), includes many conditions labeled by symptom that are appropriate for children who would also receive educational services under the educational label of ED, but there is a disconnect between the educational field where the symptomatic behavior is often first observed and the psychological/medical arena where the condition is diagnosed and treatment is prescribed.

Families and, less often, teachers serve as a bridge between diagnosis and treatment, especially in the early phase of diagnosis. It is very important for early childhood teachers to understand the diagnostic process families go through in order to understand their stress. They can then communicate with families and professionals about intervention strategies to follow in the classroom to support student success.

The DSM was revised in 2013 (fifth edition) to include more conditions for young children and to use a life span approach to reflect the changes in symptoms and behaviors as a child ages. The DSM-5 defines most childhood conditions that may occur after age 12. This latest edition lists two new disorders and one revision for young children. First, the new disruptive mood dysregulation disorder specifically identifies mood and regulation concerns for young children. One of the criteria states that the onset must occur before 10 years of age. The symptomatic behavior is far more severe than temper tantrums; it includes reoccurring

explosive outbursts that occur three or more times a week for a year.

Second, social communication disorder (SCD) is characterized by persistent difficulty in verbal and nonverbal communication for social—not cognitive—reasons, leading to impairments in creating and maintaining social relationships. Symptoms must be present in early childhood even when the behavior is not recognized until later, when demands for speech and language communication exceed the child's abilities.

Third, DSM-5 revised the criteria for post-traumatic stress disorder (PTSD) to include a subtype for preschool with specific information for children younger than 6 years of age.

Unfortunately, DSM-5 definitions are not very useful when applied to young children. They do not fit well because of the limited options for diagnosis. This latest edition does take a life span approach, and it organizes the conditions to enable recognition of symptoms across ages, but detail and depth are still lacking for diagnosing young children. The IDEA definition of emotionally disturbed children denotes "long period" as part of the definition, but that is often incongruent for young children.

In a recent publication, researchers at Harvard Child Study Center described the important role infancy and early childhood have on the long-term mental health of an individual. The brief starts with a statement that significant mental health problems can and do occur in young children. It goes on to discuss genetic and environmental situations that increase risk. In some cases, the problems in a young child's life have serious consequences for early learning, social competence, and lifelong physical health. Children who lack learning or social interactions early in life, or who are not engaged with others or activities, may suffer emotional disturbance later in life. Children at a very early age can show clear characteristics of anxiety disorders, attention-deficit/hyperactivity disorder, conduct disorder, depression, PTSD, and neurodevelopmental disabilities such as autism. Diagnosis may be difficult because a young child's response to traumatic events or emotional experiences is

very different from the responses of older children and adults.

There is special cause for concern about mental health and behavior in young children with existing high suspension rates in preschool that are racially disproportionate. According to a federal accounting of preschool suspensions, 5,000 preschool children were suspended once in 2011–2012. Both large multicenter child care facilities and preschools and small community programs are under the scrutiny of their paying customers, so that when a child engages in a challenging behavior, such as biting others, administrators may opt for a quick solution such as suspension of that child. The federal report on preschool suspensions also showed a troubling racial disparity: Whereas 18% of the preschool population in 2011–2012 was identified as Black, children of color represented 42% of preschool children suspended once and 48% suspended more than once. The report did not provide reasons for the disparity. One possible solution to the high suspension rate is professional development for preschool teachers, preparing them to improve children's social communication and self-regulation. The area of professional development for preschool teachers is in itself an issue for the fields of early childhood education and early intervention since in many settings, qualifications are far less than those of K–12 teachers. This is widely believed to be a concern, especially when working with children who have special needs.

Interventions

Interventions highlighted in this section are responses to children's challenging behaviors on a continuum based on the severity of the concerns. The teaching pyramid illustrates varying interventions as the level of challenging behaviors rises. This positive behavioral support model has strong empirical support with both individual and group interventions for children with challenging behaviors. Pharmacological intervention is sometimes used in conjunction with the teaching pyramid and positive behavior support model but is managed outside of the school environment.

Teaching Pyramid

In much of the literature about behavioral concerns for young children, the term *challenging behaviors* is used, so the focus is on the behavior rather than the child. The body of literature around challenging behaviors begins with a strong emphasis on prevention through knowledgeable preparation of the environment and educators who are responsive to children and as the foundation for social skills needed by young children to succeed in group settings. Not all children know how to share or how to change from one activity to the next. Social skills such as taking turns and transitioning from one activity to the next must be explicitly taught. Mary Louise Hemmeter and Lise Fox have created a framework called the teaching pyramid for teachers to address the social-emotional needs of young children in group settings (see Figure 1). The framework provides information, training, and resources for each level. In this hierarchy, most teachers use information in levels 1 through 3.

Interventions at level 1 of the pyramid are intended to develop and sustain a more effective teaching workforce. This level focuses on the preparation, qualifications, and professional development of teachers and other staff working with young children. An understanding of child development is the basis for level 1 interventions. Knowledge and skill increase teacher competence and confidence and reduces staff turnover.

Level 2 focuses on developing a nurturing, responsive, and supportive environment for children. Teachers learn universal strategies to provide routines and strategies to benefit all children—routines for the start of the day, transitions within the day, and specific routines for play and large group activities. This strategy informs the children and the educators about what to expect throughout the day. In turn, with a more competent responsive staff, the quality of the supportive environment improves. Teachers interact with and support each child so all children can succeed in the environment.

Level 3 of the pyramid targets supports for specific children through social interaction and communication, with a focus on preventing

Figure 1 The Teaching Pyramid Model

Source: The Teaching Pyramid model, p. 135, in Hemmeter, M. L., & Fox, L. (2009). The teaching pyramid: A model for the implementation of classroom practices within a program-wide approach to behavior support. *NHSA Dialog*, 12(2), 133–147. doi:10.1080/15240750902774718

undesired behaviors and replacing them with appropriate ones. In this environment, children learn social skills, and teachers provide supports for success. Teachers use specific interventions to prevent challenging behaviors. In short, children learn social skills and classroom routines with an emphasis on social interaction and communication in each activity throughout the day. Clear expectations are explained, and children thrive in an atmosphere of the classroom that is responsive to all.

The final level of the pyramid, level 4, is for the smallest number of children with the most severe and frequent challenging behaviors. The number is the smallest because with all the other levels from the pyramid in place, the need for more intensive intervention lessens. This level of intervention provides individualized targeted strategies for behaviors of a specific child. Interventions using behavior principles are the most effective. Applied behavior analysis emphasizes the identification of the function of the undesirable behavior in many settings, and then the intervention is designed to decrease the behavior. Specialized strategies using behavioral principles teach children specific behaviors to support the child's success.

Positive Behavior Support Model

Another intervention using principles from applied behavior analysis (ABA) is the positive behavior support model. This model grew from systematic intervention in special education classrooms and applies principles from ABA to the entire school. The model also has levels of intervention based on the need of the child. The primary level emphasizes prevention interventions that can be implemented with all children. Its goal is to reduce new cases of problem behavior. In a particular setting (school, e.g.), it lays out three to five general "rules" phrased in positive language for everyone in the setting. An example is "respect yourself; respect property; respect others." Setting up the preschool classroom with clear, simple rules in positive language is a premise of this approach. Positive reinforcement is a successful strategy to encourage preschool children to repeat a desired behavior. The goal at the secondary level is to reduce current levels of problem behavior with systematic interventions that use behavioral principles. These principles include learning the function, or cause, of the behavior a child is exhibiting. Observers note if a child is trying to escape an undesired activity or if the child is exhibiting

behaviors to gain attention of others. This level prescribes specific interventions designed to teach the student expected behaviors. All students know the expectations and consequences associated with a routine or rule. The last level, the tertiary level, seeks to reduce the frequency and intensity of behavior problems for the few students with ongoing concerns. There are fewer students needing intervention at the tertiary level, and their needs are much more severe. The intervention strategies at the tertiary level are usually individualized and delivered one-to-one.

Pharmacology

Pharmacological treatment is also used with children who have been labeled with ED and/or one of conditions from the DSM-5. Medications are used to manage behaviors, not cure them. They are administered to decrease behaviors such as impulsivity or hyperactivity or obsessive-compulsive actions. The drug prescribed is specific to the condition and behaviors exhibited. These drugs often have side effects such as sleep interference, attention interruption, drowsiness, and irritability. Teachers must be aware of the side effects and best ways to interact with the student when side effects are occurring. Careful monitoring is required by medical professionals to ensure correct dosages.

BEHAVIORAL THEORY

As apparent from the name, behavioral theory is the study of behavior. John B. Watson, credited for the development of classical behaviorism, argued for the study of observable, measurable behaviors as a means of identifying why organisms (e.g., humans, animals) engage in certain behaviors. Building on the research of Watson, Ivan Pavlov, Edward Thorndike, and other researchers who advanced the field of behaviorism, B. F. Skinner's seminal 1938 work, *The Behavior of Organisms*, provided details of his research in the 1930s and further described respondent and operant behaviors.

Respondent behaviors are involuntary, similar to a reflex, and are controlled by the stimulus introduced immediately before the behavior (i.e., antecedent). For example, the puff of air (antecedent) during a glaucoma exam elicits a blink (respondent behavior). Operant behaviors are influenced by the stimulus introduced following an occurrence of the behavior (i.e., consequence). For example, during circle-time a child raises her hand and waits to be called on (operant behavior), and the teacher praises the child for her “quiet raised hand” (consequence). Further, operant behaviors that are consistently reinforced following the introduction of a specific stimulus (discriminative stimulus) will be more likely to occur when the stimulus is reintroduced. The discriminative stimulus does not control the behavior but rather “signals” reinforcement is likely to occur. For example, the teacher says, “One, two, three, eyes on me”

(discriminative stimulus), the class responds, “One, two, three, eyes on you” (operant behavior), and the teacher praises the class, “Wonderful, everyone is ready to learn” (consequence).

The identification of operant behaviors supported a major tenet of behavioral theory suggesting learning occurs through repeated interactions with the environment (i.e., environmental stimuli). Specifically, any behavior that is not reflexive, be it academic, social, or challenging behavior, is controlled (i.e., strengthened or weakened) by its consequence. It is important to note *consequence* is typically used to describe delivery of an aversive effect, for example, time-out (e.g., “Those are the consequences”). However, the use of the word *consequence* in the behavioral field means any stimulus (pleasant, aversive, or neutral) that occurs immediately following the behavior.

Key Principles of Behavior

Important discoveries made by Skinner and other prominent behaviorists established key principles of behavior, namely, reinforcement (positive and negative), punishment (type 1 and type 2), and extinction. To understand positive and negative reinforcement, it is important to remember a few key points about word use in the behavioral field. First, the use of positive and negative does not mean *good* and *bad*. As used in behavioral terms, positive means add (+) and negative means remove or avoid (–). Second, the word *reinforcement* refers to future occurrences of the behavior. Specifically, if a behavior is reinforced, the behavior is likely to increase in frequency or maintain over time.

When positive reinforcement occurs, a stimulus (consequence) is added following a behavior, increasing the likelihood the behavior will occur again. For example, a child cleans up the block area (operant behavior) when asked and the teacher praises the child (consequence, positive reinforcement). Then, the next time the teacher asks the child to clean up, the child complies. When negative reinforcement occurs, a stimulus (consequence) is removed or avoided following a behavior, increasing the likelihood the behavior

will occur again. For example, if putting on a seatbelt (operant behavior) allows a person to avoid the seatbelt buzzer (consequence, negative reinforcement), the next time the person gets into a car he or she is more likely to put on his seatbelt to avoid the buzzer. It is important to remember that negative reinforcement is different from punishment. If negative reinforcement occurred, the behavior is likely to increase or remain at the same level of occurrence. Punishment decreases the likelihood behavior will occur again.

Similar to the word *consequence*, *punishment* is typically used by the general population to describe delivery of an aversive stimulus, for example, putting a child in a time-out. As with other behavioral terms, it is important to note that the use of the word *punishment* refers to future occurrences of the behavior. Specifically, if a behavior is punished, the behavior is likely to decrease in frequency and disappear over time. It is important to make this distinction because often the term *punishment* is misused. For example, a strategy might be identified as punishment when it is in fact reinforcing the behavior (e.g., being sent to a time-out when the behavior is occurring to avoid or escape a non-preferred activity).

Type 1 punishment (i.e., positive punishment) occurs when a stimulus immediately following the behavior is added that decreases the frequency of the behavior. For example, a child says “cat” when the teacher holds up a picture of a dog, resulting in laughs from the child’s peers (embarrassing the child). The next time the teacher holds up a picture, the child may not answer. Type 2 punishment (i.e., negative punishment) occurs when a stimulus immediately following the behavior is removed and the behavior decreases. For example, a child is removed from the slide area on the playground for pushing peers in line. The next day the child follows the slide rules and no longer engages in the inappropriate behavior. Extinction, a type 2 punishment strategy, occurs when whatever reinforced the behavior is removed and the behavior decreases and eventually disappears. For example, during circle-time a child calls out and receives teacher attention (i.e., calling out is reinforced by

teacher attention). Extinction of *calling out* would require the teacher to ignore all occurrences of calling out (i.e., calling out is no longer reinforced by teacher attention) and only provide attention when the child is engaging in appropriate behavior (e.g., hand raised and is waiting quietly to be called on).

Shaping and Modeling

All of the key principles described earlier play important roles in shaping behavior and modeling, two commonly used teaching strategies. Shaping occurs when successive approximations (i.e., each action or step closer to the desired behavior) of a behavior are reinforced, which eventually leads to learning the entire skill. For example, hand washing is usually taught in steps, with each step building on the next until the child can complete the entire task. When shaping hand washing, the first step, turning on the water, is reinforced. Once turning on the water is established, the behavior no longer receives reinforcement (extinction). Instead, turning on the water *and* putting a hand under the soap dispenser is reinforced. This process continues with each step until the child can complete the entire task. In shaping, the child's behavior is directly influenced through the use of reinforcement.

Albert Bandura's research demonstrated that learning also could occur through imitating or modeling observed behavior, such as when a child who is not yet reading imitates book reading behaviors after observing his or her parent read a book to him or her before bed (i.e., modeling book reading). Further, observed behavior that is reinforced in the environment (e.g., classroom, home, community) is more likely to be imitated than behavior that is punished.

For example, a teacher uses descriptive praise to acknowledge a child who is cleaning up the block area, "Katie is doing a great job putting her blocks away on the shelf!" After the appropriate model (Katie cleaning up the block area) is praised, Katie's peers start to clean up. One word of caution, just as appropriate models of behavior can be

reinforced and imitated (e.g., sharing, waiting in line), inappropriate models of behavior can be reinforced and imitated as well. For example, when asked to clean up the dramatic play area Rachel yells, "I don't want to!" and walks away from the center; instead of redirecting Rachel back to the task, the teacher cleans up the area and Rachel avoids cleaning up. After the inappropriate model is reinforced, Rachel's peers verbally refuse to clean up and leave their centers untidy.

Applied Behavior Analysis

Grounded in behavioral theory, applied behavior analysis (ABA) extended the work of the behavioral field to applied settings. Prior to the late 1950s behavioral research typically occurred in labs with nonhuman subjects (e.g., rats, pigeons). As the field progressed, behavioral researchers began studying the effects of behavioral strategies used with children and adults. For example, Sydney W. Bijou studied the use of different reinforcement schedules on the response rates of preschool children who were typically developing and children and adults with intellectual disabilities.

In 1968, Donald M. Baer, Montrose M. Wolf, and Todd R. Risley wrote their seminal piece describing the seven defining characteristics of ABA research: *applied*, *behavioral*, *analytic*, *technological*, *conceptually systematic*, *effective*, and *generality*. As Baer and colleagues described, the *applied* in *applied behavior analysis* signifies the importance of identifying meaningful behaviors that enhance a person's overall quality of life, putting added emphasis on the social importance (social validity) of this type of research. The next defining characteristic, *behavioral*, emphasizes the importance of targeting observable measurable behaviors in need of improvement. In addition, data should be collected on the intervention agent (e.g., teacher, interventionist) and data collectors to ensure the intervention is implemented as intended and that data collection measured the actual behavior rather than data collector bias or drift.

The next characteristic, *analytic*, focuses on the demonstrated change in the behavior, specifically, the extent to which the interventionist demonstrates a functional relation between the intervention and the change in behavior. For example, immediately following implementation of an intervention to increase child engagement during circle-time, the child's engagement increases and challenging behaviors decrease. Immediately following removal of the intervention, the child's engagement decreases and challenging behaviors increase. On reintroduction of the intervention, the child's engagement immediately improves, thus suggesting a functional relation between the intervention and favorable changes in child behavior.

Technological emphasizes the importance of detailing each element included in an intervention package to allow for its correct use by others resulting in similar outcomes (i.e., replication). Further, *conceptually systematic* suggests in addition to specific details, the description should include the principle from which the procedure was derived (e.g., shaping, extinction). *Effective* addresses the importance of interventions that produce meaningful changes in the target behavior, adding to their practical value, rather than producing minimal changes that have little social importance.

In addition to meaningful changes, Baer and colleagues emphasized the importance of *generality*, specifically, intervention effects (i.e., behavior change) needed to maintain over time and generalize to other environments, activities, and people, and/or affect changes in other behaviors not targeted by the intervention. For example, a child's use of *requesting* has more of a lasting effect if he or she is able to use the skill outside of the classroom where it was taught, in a variety of settings and activities and with a variety of people.

Conclusion

Behavioral theory and ABA continue to influence practices used in early childhood environments. For example, positive behavioral interventions and supports (PBIS) was developed using many of

the same principles grounded in behavioral theory and the ABA traditions. The pyramid model, a PBIS framework developed by two research/training centers (i.e., Center on the Social and Emotional Foundations for Early Learning [CSEFEL] and Technical Assistance Center on Social Emotional Intervention [TACSEI]) and designed to provide tiered support within early childhood environments, was identified in a 2014 policy statement from the U.S. Department of Health and Human Services and the U.S. Department of Education as a recommended practice for addressing challenging behavior in early childhood environments and as an alternative to child expulsion and suspension. PBIS and other evidence-based practices with roots in behavioral theory continue to benefit young children with and without disabilities, improving classroom behavior (e.g., functional assessment-based intervention) and child learning (e.g., Direct Instruction).

Bias

Bias in early childhood education occurs when adults or children believe and act on the idea that those of a different gender, socioeconomic status, religion, race, ethnicity, or other intrinsic characteristic is beneath them. Individuals who act on their biases often demonstrate a lack of respect or even antagonism through their interactions with individuals with whom they have a bias. Bias can be embodied in concrete actions and in thoughts and tendencies that underlie those actions. This entry examines characteristics that are associated with the most profound biases.

Types of Bias

Racial/Ethnic Bias

The most obvious and well-known bias is related to one's views and interactions with others, children or adults, as they relate to race and ethnicity. From the choice of the curriculum used in the classroom, to the teaching approach used by the teacher, to the preference for a certain type of classroom management, racial and ethnic bias can dictate all components of an early childhood classroom and determine a given child's outcomes simply based on whether or not the classroom components accommodate diverse children and families.

Gender Bias

When children or adults interact with others based only on whether they are male or female, gender bias exists. Unlike racial/ethnic bias, gender bias can be very hard to identify and, due to that subtlety, is thought of as a hidden bias. In some ways, gender bias is expected. During the early childhood years, the process of gender identity is playing out and many children behave as society expects them to, girls choosing other girls as friends and boys choosing other boys as friends. But, traditional views of girls and boys limit their interests and threaten to restrict their abilities. Children who do not conform to gender expectation in biased environments may be harmed because they lack a sense of belonging.

During the 1960s and 1970s, the women's movement spotlighted the obligation for society to nurture girls with a more equitable approach when compared to boys. Over recent years, these beliefs, along with implementation of federal laws, state laws, and social service programs, have allowed society as a whole to hold a more egalitarian concept in the education of girls and boys. Obvious stereotypical attitudes, actions, and decisions are not as common as they were 50 years ago. However, private bias, occurring away from public scrutiny that is suspected, rather than exposed, in early childhood education is more prevalent in today's profession. Though traditional gender bias has been focused on girls and women, males, both children and early childhood teachers, also face bias. Much of teachers' gender bias is unconscious, making those views and habits all the more difficult to modify.

Cultural and Language Bias

To understand cultural and language bias, one view is that they are more effectively considered together, rather than separately. When individuals are treated unfairly based on their native language and holidays and rituals that they celebrate, then cultural and language bias is present.

Curricular materials have often been criticized as being biased against children who are from the non-majority culture or who are English language learners (ELLs). For example, some materials utilize an overwhelmingly masculine tone in their use of pronouns and in depicting ideas. For patriarchal cultures (where men are the clear voices of authority), this may not be offensive; however, in cultures where families share more leadership across generations, this is an inaccurate and uncomfortable way to understand a family as a community. Further curricular bias can occur when materials speak of sports, pop culture, or environments that give children who are familiar with those concepts an advantage in understanding in contrast to those students who have not been exposed to such ideas. When curricular materials are presented as English-only learning experiences, children from families where a different home language is spoken may be

disoriented and feel as though their language (and thus a very important part of their culture) is diminished compared to English. Teachers can lessen bias in curricula by using an anti-bias approach that emphasizes deliberate cultural infusion, respecting and honoring differences as well as increasing positive interactions among all children and their family members to form a multicultural and multilingual class community.

Religious Bias

When adults in an early childhood education environment indicate that a belief, or preference not to believe in a higher being, dictates inclusive or exclusive treatment of children, religious bias exists. This particular bias can cut across cultural and ethnic biases when they are not as readily apparent. For example, a female Muslim teacher may not favor girls or boys, but she may have richer conversations with one boy more often than other children in her classroom because that child, too, comes from a Muslim family (unlike the other children in her classroom). Teachers and children alike must understand that there is a broad diversity of religious beliefs and that these beliefs can highly influence how children and early childhood professionals behave.

Because religious beliefs are often tightly aligned with moral and ethical beliefs, schools and teachers must carefully balance the amount of religious influence that exists in light of how much emphasis is given by the community it serves. Religious bias may be lessened when early childhood teachers are aware of the diverse religious beliefs within a given educational community. Curricular materials are often not specifically related to faith traditions; however, focusing on multiple perspectives that intensify similarities among people and communities may help to decrease bias in regard to religion in early education settings.

Bias Against Children With Exceptional Needs

A long history exists in regard to how children are treated based on whether they have a preexisting physical, cognitive, language, social, or emotional

impediment or enhancement. With contemporary policies in effect, such as the Individuals with Disabilities Education Act (IDEA) and the Americans with Disabilities Act (ADA), much inhumane treatment from the past has been discontinued and is almost unthinkable. Still, bias against children with disabilities exists because education professionals are unprepared to identify, effectively teach, and advocate for children and their particular needs. It is important to note that children who are gifted and talented are often overlooked as having special needs. Also, some children are identified as both gifted and having a disability or multiple disabilities.

To combat such bias, teachers are encouraged to take a more positive approach to emphasize children with special needs as part of the learning community. With sensitive teachers, children are able to understand that accommodations and adaptations are provided so that all children are able to learn in the best way possible. Such teachers avoid putting emphasis on a child's disability, preferring to place energy on positive student-teacher relationships. Generic labels are not used in talking about the children, and teachers make an effort to expose children to people with disabilities who are active, successful contributors to their communities.

How Early Childhood Teachers Can Reduce Bias in Their Practice

Proactive practical approaches that emphasize diversity, community, and unity more effectively reduce narrow thinking, lack of exposure, distrust in differences, and isolation that all have the possibility of perpetuating bias. Teachers who support children to think critically and deliberately about the meaning of prejudice and discrimination will assist them to find answers to their questions. When children have opportunities to engage in critical thinking, they are more likely to realize what is considered fair, just, hurtful, and hateful.

When children have questions about others, teachers need to provide reflective responses or help them to find answers. Engaging children with

one another about topics that adults see as sensitive may actually help children to understand the existence of differences as the positive phenomenon that it is. As children mature, there are ideas about differences that puzzle them. Their comments and questions may seem offensive to an adult, but their points are often a reflection of their levels of understanding. When teachers respond to children's misunderstanding or curiosity, children have opportunities to increase understanding of diversity and decrease prejudicial thinking. When teachers do not respond, children often take that to mean that it is not proper to talk about differences or that they have done something inappropriate. Teachers unsure of how to answer tough questions might say, "I don't know, let's find the answer together." It opens up an opportunity for both to learn something new about bias, diversity, prejudice, and discrimination.

When children are talking about bias and diversity issues, teachers must make sure to pay careful attention to what they are saying. For clarification, the teacher may want to ask some questions so that the child's perspective is clearly understood before responding. It also helps the teacher to detect hidden questions: It is important to truly know what ideas a child already knows and what the child is really asking.

When planning and implementing experiences and dialogue around bias, teachers must keep in mind the child's age and personality. Many children are not so much interested in the fact that people are different but more about why they are different. They want to know what "being different" means and what those differences have to do with them. Teachers should not ignore their developmentally appropriate curiosity because these questions and answers help them to gather information about their own personal identity and the negative impact that hurtful comments have on everyone.

Nonverbal children can be nurtured to have some understanding of bias. Children who do not speak but are exposed to visual cues and experiences are able to collect sensory input on bias. Allowing a child to touch his hair and then touch his teacher's hair or allowing a child to look in the

mirror and compare her blue eyes to her teacher's brown eyes provides an opportunity for the child to consider diversity and begin his or her thought process about bias and diversity.

Few techniques used by early childhood teachers are more powerful in combating bias in a classroom than modeling the type of behaviors and perspectives that are desired for children to adopt. Teachers must carefully observe those situations in the classroom that can readily encourage bias or deflect a child's curiosity for engaging with a diverse group of children. Books, dolls, toys, and music in the classroom that reflect diversity create a multicultural atmosphere for children.

Because children are growing and learning, teachers should not be surprised when they make comments that appear to be racist or biased in some way. What teachers should not do is ignore them without teaching proactive behavior. For example, calling other children names or saying hurtful things to others about their gender, culture, language, religion, race, or ethnicity will not be permitted. Coupled with helping children to develop empathy for all others, each time teachers intercede to remind children that we must all respect one another, they teach children how unacceptable comments like these are. Conversely, each time teachers ignore such name-calling without stepping in (sometimes because the teacher is uncomfortable with the issue), it implicitly tells children that behavior is condoned and they may continue it more openly and with greater intensity.

Proximity and interactional opportunities can do much to reduce bias in the classroom. Teachers should create ways for children to talk to, work with, and play with other children who are different from them. Even if children do not become friends through these concrete interactions, mutual respect will more readily emerge, and respect works directly against the existence of bias.

A major way for bias to take root in an early childhood classroom is through ignorance and unawareness of family differences. Consequently, early childhood teachers should make many efforts to invite their children's families into their classrooms to share songs, traditions, customs, dances,

food, stories, clothes, and holidays. Also, opportunities for families to get to know one another may decrease possibilities that children will experience biased perspectives in their homes. Children soon discover that all families, including their own, have a rich array of cultural representation in their homes and that all of them are valuable.

BILINGUAL FAMILIES

Bilingual families are complex and multifaceted. Bilingualism—the ability to speak, read, and/or write two or more languages—is not unidimensional. Also, the term *family* is complex in its membership. Bilingual families can look and act in many ways and have a wide range of language abilities and experiences within. This entry will unpack some of the different types of bilingual families, home-based language acquisition environments and situations, and the role of community and school in bilingual families' choices.

According to the 2010 U.S. Census, nearly 20% of children under the age of 5 in the United States live in a household in which no one older than 13

speaks English as a native language. However, this statistic marks only one type of bilingual family out of the many different types that exist. The common binding element among them is that at least one member of the family speaks more than one language relatively fluently.

Family dynamics, roles, norms, and values associated with each language shape how that language is used and developed. Therefore, one language may be favored over another in situations that demand disciplining a child about schoolwork, or languages may be switched from the favored language between a mother and a child when in front of the father, who is not a native speaker of the favored language.

Typologies of Bilingual Families

To consider the different types of bilingual families, we begin by examining the types of bilingualism of individual members of the family unit. Individuals can be bilingual as defined by their receptive language skills—that is, they are able to understand more than one language when it is spoken to them. Or they may be bilingual as defined by their productive language skills—that is, they are able to speak more than one language. A bilingual person may be able to read and/or write in more than one language and thus be biliterate. Additionally, receptive, productive, and literate bilingualism are all on a continuum of proficiency. A bilingual person may produce native-like spoken Spanish but be unable to read or write Spanish. Or a bilingual person may be able to read university-level Spanish texts, but unable to write Spanish at the same level. The three dimensions of production, reception, and literacy affect the type of bilingualism produced in families.

Another way of categorizing bilingual families regards the timing of language acquisition. Families that expose their children to two languages before 11 months of age create *simultaneous bilinguals*. A simultaneous bilingual child may come from a family where both languages are spoken in the home or where a caretaker speaks another language to the child. Families that

expose their children to a second language after the age of 11 months may create *sequential bilinguals*. The language environment of the home may change by the introduction of a new bilingual member, moving to a different community, or sending the child to day care or school where there is another language spoken.

Bilingual family typologies also depend on the type of bilingualism practiced by the immediate family. A family unit consisting of parents and their children may make a conscious or unconscious decision to use multiple languages or to share a nondominant language. These choices are often pragmatically based on the economic, educational, and social influences on the family unit. For example, it is possible that one or both parents speak Spanish and English; however, the children may only speak English because it is the dominant language of the environment.

Developing a Bilingual Family

Parents in a bilingual (or aspiring bilingual) family may use one of the following types of language acquisition paradigms for the child:

One Parent, One Language. In a two-parent family, each parent speaks one language to the child. For example, one parent may speak Spanish to the children and the other parent may speak English to the children.

One Parent, Two Languages. In a two-parent or one-parent family, one of the parents speaks two languages to the children. For example, the father may speak Spanish and English to the children. Often the context may influence which language the father chooses to speak. He may speak English at the dinner table when talking about the day; however, he may speak Spanish when reading a bedtime story or discussing soccer with his child.

Two Parents, Two Languages. In a two-parent family, both parents speak two languages to their children. For example, both parents speak Spanish and English to the children depending on the context.

At the dinner table or in the home they may speak Spanish to each other; however, when the family is outside the home, the parents may speak English to the children.

The type of language acquisition paradigms are fluid: The strategies may switch from situation to situation and are likely to evolve over time. Therefore, it is not rare to find two siblings with different language skills, due at least in part to switches in the language acquisition paradigm.

In addition to the immediate family, extended family members also have an important influence. Thus, the family unit may include members such as grandparents or non-relative caregivers who are bilingual. Passing bilingualism on to children is often governed by family structure, modes of caregiving, and ideas about child care. Who speaks what to whom and when helps determine how bilingualism is passed from older family members to a younger family member, from parents to children, or from grandparents to children. Also of importance is how the different languages are used to get the work of family done.

The bilingual family member's role, identity, and immediacy will directly influence the exposure of other members, such as young children, to multiple languages. If a Polish-speaking grandmother lives with and is the primary caretaker of her grandchildren and speaks Polish with them, the children will learn to communicate in Polish. This could be so even if the parents do not speak Polish, because when they were growing up, English was the only language spoken in the home by their parents (a generational jump).

Person-to-person communication in a family unit is the primary means of language learning and acquisition. Research has shown that young children do not learn a second language, or even a first language, through interaction with multimedia, television, or computers alone. Meaningful, interactive, and linguistically rich communications with people are critical to developing more than one language in early childhood. Families often provide that support.

Bilingual abilities within a family unit may be different for different family members. Children will learn to speak a language based on their exposure

to the language and the child's perception of the language as a meaning-making tool.

Bilingual Practice

Very young children associate a specific language as a way to communicate with a specific person in their lives or a specific context. For example, a 2-year-old would believe, "This is how I communicate with Grandma" while an older child would understand, "I use Spanish to communicate with Grandma and English to communicate with Mommy." Young children recognize and distinguish between two languages and can accurately code-switch (i.e., change from one language to another) in conversation. Code-switching is developmentally appropriate for young children as they learn to speak two languages, and it is a normal practice in bilingual families.

Bilingual families may code-switch for many reasons, for example, to emphasize a word or idea, to repeat a word or phrase for understanding, to interject into an established conversation, to create social distance or create boundaries, to exclude others from a conversation, to connect a conversation to a previous conversation, or to create a special bond with the other person. (For further explanation, please see Baker, 2006, p. 54.)

Young bilingual children are quite flexible in their communicative strategies. Children will usually elect to communicate in the adult's preferred language. For example, in bilingual families, a child may observe a bilingual parent speaking English. Using this information the child may decide to communicate with the parent in English, even if the parent speaks to the child in Spanish.

For many families, bilingualism is used as a marker of membership in a community or family. The language used at home or for family-based activities is part of the family's identity. It is through the family language that the family supplies funds of knowledge or family norms, values, and beliefs.

Being bilingual in early childhood is not magical but takes a lot of hard work and planning. Oral language development in early childhood is closely associated with reading and writing success in elementary school. Although the language development

of bilingual children is similar to that of monolingual children, it is not the same. There is no connection between language or cognitive delays and bilingualism. Bilingual children have many cognitive, social, and linguistic advantages over monolingual children.

The language development of each bilingual child differs based on his or her family language environment. The family language environment will be uniquely reflected in a child's language proficiency, vocabulary, phonology, and syntax. When and how a child is exposed to two languages in the home will affect how they learn a new language in school. For example, if a father speaks Spanish to the child but he is not a primary caretaker or does not use Spanish frequently and in meaningful ways with the child, the child's Spanish language development will reflect the quality and quantity of interactions with the father. Because each family's language use and environment is unique, understanding the quality and quantity of each language is important in understanding how a young child's bilingualism develops.

To understand the whole child and his or her educational strengths and needs, we need to carefully consider the many components of family bilingualism.

BIOECOLOGICAL THEORY

Bioecological theory, developed by Urie Bronfenbrenner, consists of a complex system integrating four fundamental components (process, person, context, and time) involved in the course of human development. This entry briefly summarizes the three phases in the development of bioecological theory and presents some of its principal concepts. It focuses on the importance of proximal processes in early childhood, emphasizing the conditions under which they can be predictive of good developmental outcomes for children. It also points out the theory's importance for public policies.

A Brief History of Bioecological Theory and Its Main Concepts

Toward the end of the 20th century, the scientific community was introduced to the final and most current version of bioecological theory. Although some researchers believe that Bronfenbrenner's

main contribution was his book *The Ecology of Human Development: Experiments by Nature and Design*, published in 1979, and that his research focused on the contexts in which people live, this was not what the author himself thought. Having published this book he continued to revise his thinking until the complete version of the theory was published in a chapter written with Pamela Morris for the *Handbook of Child Psychology* in 1998, and republished, with minor changes, in the next edition of the handbook, in 2006.

During its lengthy development, the theory encompassed three clear phases (1973 to 1979, 1980 to 1993, and 1993 to 2006) and was never simply a theory about contexts and their interconnections. In the first phase, Bronfenbrenner sought to understand the ecology of human development. That is, he wanted to know how persons were influenced by the changes occurring in their environments and how they themselves changed their environments. In 1975 he thus described in some detail ecological contexts and defined development as “a function of interaction between the developing organism and the enduring environments or contexts in which it lives out its life” (Bronfenbrenner, 1975, p. 439).

During the 1970s, Bronfenbrenner criticized how developmental psychology was conducted at the time and the limited contribution of its findings for public policy. A decade later, he analyzed the various theoretical models then in mode to explain human development. The description of these theoretical models, and his plea for greater use of models that included an assessment of process, formed the basis of his writings during the second phase and furnished the base on which he constructed the final version of his theory.

The meaning of the word *process*, ever-present in Bronfenbrenner's writings since the early 1970s, changed considerably over the course of the theory's development. Earlier understood as the ways in which the organism affected and was affected by its environment, and then treated as the mediating link between some aspect of the context and an outcome of interest, it took on a very specific meaning from 1993 onward.

In the final phase, proximal processes were considered the major and greatest influence on a person's development, the main concept of bioecological theory, and Bronfenbrenner and Morris defined them as "processes of progressively more complex reciprocal interaction between an active evolving biopsychological human organism and the persons, objects, and symbols in its immediate environment" (Bronfenbrenner & Morris, 2006, p. 797). Proximal processes are the types of everyday activities and interactions in which developing individuals are typically involved. Bronfenbrenner mentioned peer-peer interaction and reading with adults as examples. He also argued that proximal processes are influenced by the characteristics (a) of the developing person and those interacting with him or her, (b) of the contexts (both local and distant) in which the developing person is situated, and (c) of the time during which the person is developing. The integration of proximal processes, person characteristics, contexts, and time (PPCT) thus form the operational model of Bronfenbrenner's theory.

Bronfenbrenner considered person characteristics not only to be the product of human development but also its producer, thanks to their ability to instigate proximal processes. He classified these characteristics as force, resource, and demand and noted that each can be generative or disruptive to proximal processes and thus development. A child who comes to school motivated to read (force), has had plenty of past reading experiences (resource), and who looks like he wants to read (demand) will influence, positively, reading with his teacher. Another child, who thinks that books are boring, perhaps because of her past experiences with them, and signals her dislike of reading will also influence proximal processes, although in a disruptive way. The teacher's person characteristics are equally important; a teacher who is motivated to encourage all children to have a love of reading, who has experience with children who come to school uninterested in reading, and who signals her willingness to help those unwilling children will help to create generative proximal processes far more than will another teacher who

is less motivated, has less experience, and signals her exasperation with children who appear to lack interest in reading.

From the 1970s onward, Bronfenbrenner categorized context as four types (microsystem, mesosystem, exosystem, and macrosystem), but the microsystem (the context in which developing individuals are situated) became more significant in the third phase, for it is here that proximal processes occur. Given that development happens in more than one microsystem, Bronfenbrenner argued that it makes sense to study the relation between proximal processes taking place in different microsystems—a mesosystem. Contexts at a broader level also influence development, albeit indirectly. Bronfenbrenner characterized the exosystem as a relation between two or more microsystems, only one of which includes the developing individual under consideration. The prototypical example of an exosystem is a parent's workplace, if her child is the developing individual of interest. An example of an exosystem effect is when a mother's problems at work cause her to be irritable with her child at home. The macrosystem, for its part, consists of the culture-wide values, ideologies, and beliefs that influence development by their effects on the behavioral standards displayed in the microsystems.

The final property of the PPCT model is time. Even in the 1970s the theory was developmental, but through much of the 1980s Bronfenbrenner made this fact, and the importance of time at different levels (the need for longitudinal research and studies taking into account the passage of historical time), increasingly explicit. In the third and final phase of the theory's development, time was classified as microtime (continuities and discontinuities in interactions occurring during proximal processes), mesotime (how often these interactions occur over weeks or months), and macrotime (events occurring in the society either currently or in earlier generations). Each of these is likely to impact proximal processes and therefore developmental outcomes.

Bronfenbrenner's definition of human development also broadened over time. In bioecological

theory, development is defined as “the phenomenon of continuity and change in the biopsychological characteristics of human beings, both as individuals and as groups. The phenomenon extends over the life course, across successive generations, and through historical time, both past and future” (Bronfenbrenner, 2001, p. 6964).

Proximal Processes in Early Childhood

The family is the primary context where most children first experience proximal processes. From their first days of life, they need their parents' attention and time for development to proceed optimally. The earliest proximal processes have to do with feeding, changing, cleaning, and social exchanges, all of which will be influenced by the baby's early temperament (is he calm and easily soothed or fussy and resists being held?), by the mother's characteristics (does she have previous experience with babies, is she stressed because of lack of sleep or worried about not having employment, etc.), and by the context in which those interactions are happening (in a hospital because the baby was born premature, at home in pleasant surroundings, or in a setting that is totally chaotic).

Providing more detail about the manner in which proximal processes impact children's development, Bronfenbrenner stated that they need (a) to relate to one or more people who are committed to their well-being and with whom they develop a strong and mutual attachment; (b) to internalize the activities and affective feelings so as to be motivated and interested in engaging in new activities in their setting; and (c) to have a family environment in which there are persons other than the parents or caregivers who reinforce, encourage, and support the dyadic interactions within the setting.

Bronfenbrenner discussed the role of “a third party” in bioecological theory, much as he had referred to a “second-order effect” in the first phase of his theory, calling attention to the existence of systems of relationships. Each member of a family influences each of the others, particularly when taking on a new role, or going through an

ecological transition, or simply by becoming more stressed or less absent. He thus characterized proximal processes as involving a complex system of social relationships.

Subsequently, children are likely to broaden their experience of contexts, frequenting other settings and expanding their relations with other people. The various microsystems in which children actively participate characterize their mesosystem. Grandparents' house, preschool, and the peer group come to be settings in which different types of proximal processes may occur. The ways in which children are accustomed to acting and interacting with others at home may well be different in each of these other settings. Consider an only child who spends most time at home with a parent or grandmother, and is used to the proximal processes established there, who then is placed in a preschool setting with adults who have different ways of organizing interactions and with peers with whom other proximal processes are established. These different contexts function as a system, and the greater the capacity is of one context to influence proximal processes in other spaces, the more important it is for children's development.

The success of relationships established in each new space will depend, to a large extent, on the quality and the depth of relationships experienced in the family, children's first microsystem. Their initial relationships do not simply provide them with the content of individual growth (not just for the children but also for the adults with whom they relate) but also the wherewithal to foment new relationships and new positive outcomes in their development. The resulting experiences of relationships with their parents or other early caregivers therefore provoke a cascading effect, providing the basis for future relationships, among other things, because they are capable of actualizing children's individual characteristics necessary to start new relationships, provide the cognitive and emotional capabilities to distinguish among different settings, and provide positive models of social interaction.

“Third party” influences, mentioned earlier, can also carry across contexts. Glen Palm and Jay

Fagan studied parents' participation in the school life of their children enrolled in a Head Start program and found that some mothers (the third party in this instance) negatively influenced fathers' engagement with their children in school. The authors found that even fathers who were highly involved with their children at home did not participate in the program and that the mothers discouraged the fathers' participation. The mothers viewed such participation as not part of their traditional social values (a gender-based division of labor) and thereby hampered fathers' engagement in school activities with their children.

Bronfenbrenner's Contribution to Public Policy Related to Children and the Current Impact of His Theory

Bronfenbrenner played an important role proposing and evaluating public policy in the United States, writing papers about the causes of youth alienation and the poor consequences of treating families in poverty as having "deficits." As a youth, he had already seen how policies for institutions for people with mental health problems could help or hinder their development, and he firmly believed that family policies more common in parts of Europe should be adopted in the United States. He thought that state intervention, with its power to formulate, implement, and manage social programs, offered children and adolescents the opportunity to change the course of their development.

It was this belief that led Bronfenbrenner to be highly influential in the creation of one of the most important social programs for children of poor families in the United States—Head Start. He argued before the U.S. Congress and President Lyndon B. Johnson that children were influenced not only by parents but also by the community and state, and that the United States needed to create a program that would give poor children the opportunity to start their school life from a stronger position.

Bronfenbrenner's theory and his example of fighting for better conditions for children continue to motivate researchers and those interested in public policy. Bioecological theory has become an

important reference for studies in fields such as psychology, public health, social work, and education. His propositions regarding the necessity to take seriously the everyday activities and interactions in which children engage, and how these activities are mutually influenced both by individual characteristics and the multiple contexts in which children are raised, provide strong theoretical support for their study. As such, bioecological theory has permitted, among other things, a broadening of its theoretical concepts, a rethinking of research methodology, and the proposing of interventions for the greater protection of vulnerable individuals and families.

Another positive aspect that his theory occasioned was the closer link of science with the daily lives of people, primarily of children and adolescents. Bronfenbrenner's hope that science could bring real benefits to people's lives was what motivated his entire career.

BLACK BOYS, EARLY CHILDHOOD EDUCATION AND

Statistics continue to show that, overall, Black boys are faring worse than their peers in education, social, and economic domains. Regardless of socioeconomic factors, the achievement gap between Black children and their White peers emerges soon after birth and continues throughout childhood.

There are more than 40 million children under age 10 in the United States, approximately 3.4 million of whom are Black boys, according to the 2010 U.S. Census. (In this entry, *Black* is used interchangeably with *African American* to be inclusive of children from the African diaspora.) Many of these Black boys are struggling and falling behind their peers in social, academic, and, ultimately, economic progress. In fact, Yumiko Aratani, Vanessa Wight, and Janice Cooper in their 2011 National Center for Children in Poverty report show the achievement gap between Black children and their White peers appears as early as 9 months, continues throughout childhood and beyond, and exists independent of socioeconomic factors. The Black–White gap is further exacerbated by the relationship between race/ethnicity and such other sociodemographic factors as family income and structure, maternal education, and teen parenting—each of which seems to impact Black boys more severely than other racial groups.

In the first five years of life, Black boys compared to White children are more likely to live in poverty, have less educated and more depressed mothers, and live in single female-headed households. Based

on the 2010 U.S. Census, more than 40% of Black boys under the age of 5 live in households below poverty compared to 15% of White boys. Other risk factors potentially associated with the early gap between Black boys and their peers include the high likelihood of their being born at low weight and prematurity, a lack of access to health services and nutritious food, and high exposure to violence inside and outside the home.

These facts are in sharp contrast to research that provides extensive evidence concerning the importance of the early years for children's long-term outcomes. Evidence shows that children who attend high-quality (i.e., intellectually stimulating and enriching environments that include interactions with sensitive and nurturing educators) early care and education programs (ECE), especially those from poor households, are likely to benefit from these high-quality early learning experiences. However, these important benefits of early childhood do not translate to a reduction or eradication of the achievement gap between Black and White children. Studies show that although Black children are likely to attend ECE programs, those programs are less likely to be of high quality, thus potentially contributing to the "gap." In other words, Black children compared to their White peers are likely to attend programs with less well-educated teachers, poorer physical environmental quality, weaker teacher-child interactions, and poorer instructional quality. While many questions are still outstanding regarding how best to support the development and learning of young Black boys in ECE programs, additional questions remain about the cultural and gender relevancy of ECE programs.

Cultural and Gender Mismatch Between ECE Teachers and Black Males

The ECE workforce is comprised predominantly of White females. Although the gender and race/ethnicity of an ECE teacher do not mean that that individual is unable to provide culturally rich, intellectually stimulating, and responsive instruction to and interactions with Black males, some

studies indicate that the cultural mismatch between teachers and subgroups of children may contribute to the poor quality of care and education that Black boys are likely to experience.

Given the limited number of Black male teachers, Black boys are less likely to be exposed to academically oriented adult male role models. This also likely results in ECE programs being less boy-friendly because of the programs' focus on early verbal mastery, fluency, and fine motor skills rather than gross motor movement and flexible language use. As James Earl Davis (2003) has noted:

One reason commonly mentioned for the disengagement, alienation, and poor academic performance of Black males is that they perceive most educational activities as feminine and irrelevant to their masculine identity and development. Furthermore, it is also believed that schools, specifically teachers, impose a feminine culture on males that induces oppositional behaviors. (p. 519)

Thus, there is a need for a deeper examination of how the structure (including staffing patterns), processes of learning (i.e., curriculum), and ways of learning (gross versus fine motor, indoor versus outdoor learning) may inhibit the optimal learning of Black boys.

Culturally Relevant Pedagogy and Practices in ECE

Black males are shaped by their "rich cultural perspectives that are rooted in early experiences with their families and communities" (Day, 2006, p. 97), but these cultural assets are rarely recognized or incorporated in ECE programs to support Black boys' excellence. However, there is limited research on the impact of culture on children's development and learning. This is especially the case in addressing whether high-quality ECE means the same thing for all children, especially Black boys. There is a particular need to understand the intersection between culture and socioeconomic status, especially in light of the environmental risk factors Black boys are likely to

experience as a result of structural and historical racism. Meanwhile, studies focused on older children demonstrate that culturally responsive pedagogy is associated with better academic outcomes for minority children.

Although limited, some studies focused on preschool children show that preschool programs that incorporate an Afrocentric perspective are associated with better cognitive outcomes (e.g., Hale-Benson, 1990). This suggests that in the early years when children are inextricably intertwined with their family and cultural background, ECE programs should seek to ensure that they incorporate culturally responsive instruction that supports Black boys' culture and gender identity, subsequently establishing a strong foundation for learning and developing.

Thus, while studies show the value of high-quality ECE programs for supporting children's development, questions still remain about aspects of ECE that are particularly beneficial for promoting excellence in Black boys. Research is needed regarding (a) the importance of Black educators in ECE, particularly Black males; (b) impact of culturally relevant pedagogy and practices in ECE settings; and (c) cultural relevance, meaning, and impact of current definitions of "high-quality" ECE.

BLENDING FAMILIES

Between 1960 and 2010, the percentage of children living in families with their married biological parents dropped from 85% to 69%. Children today live in a range of family contexts, including

stepfamilies and blended families. In this entry, the word *stepfamilies* refers to families in which one parent remarries but no additional children are born as a result of this union. The word *blended families* is used to refer to families in which one parent remarries and then has additional children with the new spouse or both spouses have children from their previous marriage, such that some of the children in the family are biologically related to both parents and some are biologically related to just one parent. Given the current prevalence of these alternate family forms, it is essential that practitioners in educational settings understand the implications of growing up in these family contexts for children's environments and outcomes.

The Contemporary Family Context

Changes in family structure in the United States mean that children today are growing up in a number of different family contexts. While the rate of children living in homes with two biological parents is decreasing, other types of family structures are becoming more common, including stepfamilies, blended families, and single-parent families. Two trends are responsible for this diversification: first, the growth of the divorce rate between 1960 and 1980, and second, the increase in nonmarital childbirth between 1960 and the present. In 2013, 40.6% of all births were to unmarried women. In the same year, 40% of people who got married had been married at least once before, and many of these individuals had children from previous marriages. As a result, not only are more children living in nontraditional family types, but because of the rise in divorce and separation rates, most children today will experience one or more changes in family structure that require adaptation and coping.

Family Structure and Child Development

Concern over children's well-being in nontraditional families has spurred a significant body of empirical research on the effect of family structure on children's development. On average, children in single, step, and blended families tend to have

worse socioemotional and cognitive outcomes than those in two biological married-parent families. Specifically, these children tend to experience greater levels of aggression, depression, and anxiety; more delinquency; and more problems in school, both behaviorally and academically. Moreover, even though children in step and blended families have an additional parent compared to those in single-parent families, children's outcomes in these families on average still lag behind their counterparts in two biological married-parent families. Some studies even find that children in step and blended families tend to fare no better socioemotionally than those in single-parent families.

Four primary mechanisms have been proposed to explain how family structure may impact children's well-being: economic resources, parenting time and quality, family conflict and stress, and social selection.

Economic Resources

Step, blended, and single-parent families have lower household incomes on average than do married biological parent families. As a result, children in these families typically receive fewer educational investments and other enrichments that are associated with enhanced child outcomes. This disadvantage in economic resources accounts for as much as 50% of the difference in academic outcomes between children in single-parent homes and children in married-parent homes.

Children in nontraditional families receive fewer economic resources not only because their families have lower average incomes but also because parents in nontraditional families allocate fewer available resources to children. For example, one study showed that even among families with similar incomes, households with a greater number of children with stepparents also make fewer investments in food consumption, and another found that compared to married parents, cohabitating couples with children tend to spend less on health care and education. For both reasons, then, weaker economic resources are considered a primary process by which family structure impacts child development.

Parenting Time and Quality

Parents in step, blended, and single-parent families also interact in less sensitive and stimulating ways with children than married biological parents on average, and these differences have been shown to impact children's developmental outcomes. Among children in families with stepparents or with cohabitating mothers specifically, children on average experience lower parental sensitive caregiving, warmth, and nurturance compared to children in married biological parent families.

It is not only the quality but also the quantity of time that caregivers spend with children that differs in step, blended, and single-parent families relative to married biological parent families. Children in step and blended families spend less time alone with biological mothers and, not surprisingly, less time with their biological fathers than children in married biological parent families. Stepfathers do not fully compensate for this loss in parental time because they typically spend less time with children than do resident biological fathers, in part because the roles and responsibilities of stepfathers are less socially structured and more fragile. Within blended families specifically, however, the amount of time that fathers spend with biological and nonbiological children is roughly equal. Thus, children in blended families on average receive greater time investments from parents than children in stepfamilies. However, fathers in blended families have been shown to invest more time in children when they are married to the mother as opposed to cohabitating, indicating that even within blended family types there exist differences in paternal investments. Such differences in maternal and paternal time spent in activities with children may partially explain the fact that children in these family types have higher than average levels of problem behaviors.

Family Conflict and Stress

Another mechanism through which family structure might impact child development is family conflict and stress. Children can experience two different types of parental conflict: intrahousehold conflict (conflict between parents residing in the

same house) and interhousehold conflict (conflict between parents residing in separate households). Children living in step and blended families are at risk for exposure to both types via concurrent interhousehold conflict between separated biological parents and intrahousehold conflict between biological parents before the separation and possibly between a biological parent and new stepparent. It has been theorized that this exposure might explain the link between family structure and developmental outcomes.

In families where biological parents eventually divorce or separate, children show substantial academic, emotional, and behavioral problems even before the disruption occurs, suggesting pre-disruption intrahousehold conflict may account in part for the negative outcomes associated with family dissolution. In such cases, parental divorce may actually alleviate some of the problems that children were experiencing during the parents' marriage, a hypothesis supported by the fact that behavior problems tend to dissipate somewhat once the parents separate. Furthermore, children from married biological parent households in which there is high parental conflict also experience greater levels of behavior problems than other children of married parents. Thus, parents' staying together in high-conflict households does not buffer children from the negative effects of intrahousehold conflict.

Social Selection

Finally, it is possible that social selection accounts in part for differences observed in outcomes among children from various family structures. Social selection refers to the idea that parental characteristics that contribute to family instability may also impact parenting and children's home environments more generally, which could induce a spurious association between family instability and child well-being. Examples of such characteristics include poor emotional or behavioral health, interpersonal problems, low income, low education, and low cognitive aptitude. Such differences between family types might drive variation in child well-being irrespective of family

type, meaning that it may not be family structure differences per se that drive the differences in child outcomes across family types.

When these types of characteristics are accounted for, links between family structure type and child well-being become weaker, indicating that these underlying characteristics play some role in the observed differences in well-being of children from differing family structure types. However, despite the threat to causal inference these characteristics may impose, studies that have used robust techniques for addressing the influence of selection, such as comparing siblings discordant on family structure experiences and examining individual changes in children's outcomes over time, have found that parental separation and family instability negatively impact children's behavioral, academic, and socioemotional outcomes over and above the effect of selection.

Family Structure Changes and Child Outcomes

Another reason children in nontraditional family structures may fare worse developmentally than those in married biological parent families is because family change itself necessitates a reorganization of roles and disrupts the system of family relationships and, in doing so, may undermine parent and child well-being. In general, children who have experienced such changes have poorer cognitive and behavioral outcomes than children in stable married biological parent homes, though effects on behavioral outcomes are usually stronger. The literature on transitions into step and blended families, versus single-parent families, is more mixed, with some studies finding transitions into blended families are associated with decreases in behavioral and cognitive outcomes and others finding these transitions are associated with improvements in socioemotional and educational outcomes, at least during middle childhood or early adolescence. The number of transitions into different family types may also play a role in behavioral outcomes, with children who experience more transitions faring worse than those who experience fewer.

The most rigorous research to date on this topic has found that the impact of family structure change depends on the context of the child's life in which these changes occur. Specifically, changes in family structure experienced during the first five years of life are more predictive of children's behavior problems than such changes experienced later, likely because children are most susceptible to their environments during this period. In addition to children's age, the impact of family structure change seems to depend on the type of change the child experiences and the family's income level. For children with married parents, moving into a single-parent family is associated with significant and long-term behavior problems, whereas for children with unwed biological parents (i.e., cohabiting parents), the same transition is linked to smaller and more short-term behavior problems. Additionally, such transitions seem to impact children from higher income families more than those from low-income families. That is, moving from a two biological parent family into a single-parent family is associated with increases in behavior problems for children in high-income families but not for those from families at other income levels, and movement from a single-parent family into a stepfamily for the same children predicts a decrease in behavior problems. Thus, across studies, results indicate that when children are from unmarried parent and/or low-income parent families, family structure changes are less impactful, perhaps because they are more normative in these contexts.

This line of research also suggests that movement into a blended family may not be associated with long-term changes in children's behavior problems when experienced during middle childhood. Indeed, relative to staying in a single-parent family, moving into a step or blended family type during middle childhood following parental divorce or separation may significantly benefit children in terms of their socioemotional well-being.

BRAIN DEVELOPMENT

The brain undergoes remarkable change in early childhood. Brain development begins in the womb, and much of the work is reserved for the first few years of life. Brain development is shaped by experience; this is especially true in early childhood where environmental influence can impact long-term developmental trajectories. An understanding of brain development helps explain young children's tremendous capacity for learning, behavioral regulation, and socioemotional competence.

Early Brain Development

Brain development begins soon after conception. Within the first few weeks of conception, the neural

tube develops and will eventually form the brain and spinal column. The major developmental task of the neural tube is to grow neurons, and this is achieved at a rate of 100,000 to 250,000 per minute. Neurons then specialize and migrate to genetically predetermined locations; differentiated neurons will later perform unique functions and comprise different regions of the brain. Four weeks after conception, early brain function is detectable and the head accounts for 50% of total fetal length. By birth, the brain contains over 100 billion neurons. It was once thought that neurogenesis, or the forming of new neurons, occurred only in utero. We now know that adults have the capacity to form new neurons (termed *neurogenesis*), but neural growth is never as prolific as in the womb. More important than the quantity of neurons is the strength of connections between neurons.

A complex interconnected neural network is formed with dendrites drawing information toward neurons and axons passing that information along. Axons from one neuron nearly connect to dendrites from another neuron at synapses (the location or gap between the two nerve fibers). Neurotransmitters (chemical signals) or electrical currents flow along neural pathways to achieve communication between neurons. The main functions of the neural network include receiving and interpreting information, making decisions about that information, and planning and carrying out actions based on the information. For example, if a child picks up a hot object, nerve cells send a signal to the brain that is interpreted as pain, the child decides to remove the sensation of pain, enacting a plan to release the object. The speed and accuracy with which neurons communicate is vitally important to brain function.

Brain Plasticity

Although a newborn baby has billions of neurons at birth, the connections between and among neurons are formed largely after birth as a result of experience. The neural pathways that children employ, for example, to bring a spoon from a bowl

to the mouth, will be strengthened with opportunity for practice. In order to strengthen connections between neural pathways that are frequently engaged, the brain undergoes two important processes in the first few years of life. First, often used neural pathways are coated with a fatty substance termed *myelin* (myelination). The myelin sheath insulates axons and speeds communication between cells. Second, from birth through age 3 years the brain undergoes a period of prolific overproduction of synapses (connections between neurons, called synaptogenesis) peaking at about 15,000 synapses per neuron, double the synapses found in an adult brain. Neurons that do not form interconnections with other neurons undergo a process termed *synaptic pruning*. In other words, unused synapses, and by extension neurons, are eliminated. Consider the following analogy: Newly formed neural connections can be likened to a forest path. If a particular path leads to a desirable destination, it will be frequently traveled, until it grows into a dirt road, then a paved road, and eventually a super-highway. If a forest path leads nowhere or is rarely traveled, it will eventually become overgrown until it is indistinguishable from the forest. Synaptic pruning of less used neural pathways creates space for well-used neural pathways to increase in size, speed, and function. Despite synaptic pruning, the brain triples in size from birth through age 2. The brain of a 2-year-old is 75% the weight and size of an adult brain. By age 5, the brain is 90% of its adult weight.

Taken together, the processes of synaptic flourishing and subsequent pruning, along with myelination of neural pathways that are activated by experience, describe how the environment shapes brain development. The ability to shape brain architecture based on experience is called brain plasticity. Some aspects of brain development require experience in order for new learning to occur—termed *experience-expectant learning*. Examples include wiring of the senses or first language acquisition. Experience-dependent learning describes additional learning that may occur, for example, by growing up in a particular culture, but is not required for the brain to develop optimally.

The brain is considered most plastic, or malleable, during early childhood. This malleability means that the brain is primed to learn from new experiences and has the potential to recover from early injury or trauma. Brain plasticity also means that the brain is especially vulnerable to negative environments and experiences in early childhood. Early experiences that shape brain development can alter long-term developmental trajectories and affect multiple domains of functioning across the life span.

Migration, Specialization, and Lateralization

Not all regions of the brain develop at the same pace. Beginning with neural migration in early fetal development, neurons begin to specialize and eventually perform unique functions. The brain matures from back to front and right to left. The hindbrain forms the brain stem and cerebellum. The brain stem develops early and regulates autonomic functions, including breathing, heart rate, blood pressure, and digestion, as well as sleep and hunger. The brain stem is relatively mature at birth so that the infant can function independently. Primitive reflexes, present at birth, are generated in the brain stem and cerebellum. The cerebellum controls motor movement, coordination, and learning. The cerebellum is organized and myelinated following birth.

The forebrain divides into cerebral hemispheres. In early childhood, hemispheres begin to lateralize or perform distinct functions. By middle childhood, the left hemisphere is more often associated with language-based skills and processes information at the detail level. The right hemisphere engages in spatial reasoning, including mathematical thinking and artistic expression. The right hemisphere processes information globally (i.e., big picture thinking).

Subcortical regions include the thalamus, basal ganglia, and limbic system. The thalamus is responsible for sharing information between brain regions and aids in the control of attention and sleep. The basal ganglia are implicated in motor control, and the limbic system represents the emotional center

of the brain where emotions including fear, pleasure, and anger are generated. The development of the limbic system across the first several years of life helps explain why irrational fears and nightmares are hallmark features of early childhood. The limbic system interacts with the hippocampus to store and reproduce emotion-laden memories. The cerebral cortex is the top layer of the brain comprised of four regions or lobes that also develop from back to front: the occipital, parietal, temporal, and frontal lobes. The cerebral cortex enjoys a protracted developmental trajectory, with the prefrontal cortex—housing executive functions and responsible for self-regulation—developing in early childhood but not fully mature until early adulthood.

Interconnected and Experience-Dependent

Regions of the brain differentiate to perform unique functions but do not operate in isolation to achieve discrete developmental tasks. Rather, multiple areas of the brain are activated and coordinated to achieve goals. Communication between different areas of the brain requires experience and opportunity for practice. The corpus callosum connects the two brain hemispheres and develops approximately 800 million nerve fibers that help coordinate brain function by the end of early childhood. The building of complex and coordinated infrastructures explains why development is protracted and why motor, cognitive, language, emotional, and social development are interconnected.

For example, motor development is relatively complex and requires interconnections between multiple regions of the brain. The womb offers some opportunity to practice motor movement and coordination (e.g., fetal thumb sucking usually predicts later handedness). In the first years of life, however, much more opportunity to practice motor control leads to connections with cortical regions of the brain associated with motor planning and execution. The cerebellum is well developed at birth, but it continues to produce new neurons at a higher rate than other brain regions. In order to walk, children must lay neural pathways that connect muscle movements. This activity

occurs not only in the cerebellum but also in the primary motor cortex, where motor control occurs. Walking additionally requires some information about the environment, including depth perception, which comes from the parietal (spatial processing) and occipital (visual processing) lobes. Yet spatial development, specifically depth perception, is spurred by earlier motor milestones, including the ability to sit upright and crawl. Once children are mobile, they develop an appreciation for object permanence, a major cognitive milestone. With object permanence comes the understanding that caregivers continue to exist when out of sight, and what follows is separation anxiety, a milestone in emotional development. In sum, developmental processes are intertwined, and experience with the environment serves as a catalyst for new skill acquisition.

Gene–Environment Interaction

Only a few decades ago, scientists debated whether aspects of children's development (e.g., language, temperament) were a result of nature (i.e., genes) or nurture (i.e., early social environments). Subsequent research has uncovered an answer far more complex. Whereas genes are encoded and inherited through our DNA, early experiences determine gene expression. Humans are born with about 23,000 genes inherited from their parents. Genes are considered the blueprints for development, and the epigenome regulates the expression of the genes within a person's genome. Consider the example of schizophrenia: If one identical twin develops schizophrenia, the other has about a 50% chance of also developing schizophrenia. Using the old nature versus nurture language, we would imagine that 50% of the risk for developing the disease is passed on through genes and about 50% is determined by the environment. In fact, both twins are born with the exact same genetic predisposition for the disease but the epigenome switched on the gene or genes associated with schizophrenia in one twin and not in the other as a result of some environmental input. Chronic stress, psychotropic drug use, and even fetal exposure to influenza are all factors that contribute to

the genetic expression of schizophrenia. Epigenetics describes how experiences can alter brain architecture as well as why early brain development is marked by critical periods. Some genes are open to epigenetic modification throughout life, whereas other genes can be modified only during certain developmental phases.

Critical and Sensitive Periods of Development

A critical period of development describes a phase when children are uniquely prepared to learn a new developmental task. If the window of opportunity is missed, the brain fails to wire and the ability to perform that particular function is lost forever. For example, an infant born with cataracts will fail to wire up the visual cortex if no visual stimulation occurs during the critical period of development. Animal studies reveal that infant animals experimentally deprived of visual stimulation fail to acquire the ability to see if the deprivation occurs during the synaptic flourishing and pruning phase in the visual cortex. In human infants, the ability to see is permanently lost if wiring does not occur in the first few months of life, even if the opportunity for visual stimulation is reintroduced after synaptic development. Similarly, animal studies and human case studies confirm that in the absence of opportunity to hear sounds that vary in tone and volume, the auditory cortex will fail to wire as intended. Devastating examples of profound early neglect also point to early childhood as a critical period for first language acquisition. In rare cases of complete isolation or abandonment, children fail to acquire grammar and syntax beyond early childhood even with intense remediation.

Critical periods of development describe a time when the input experience must occur for the brain to wire as intended, whereas *sensitive periods of development* describe a time when the input experience and subsequent wiring optimally occur. For example, in early childhood when neurons and neural connections are being formed in the language areas of the brain, children appear especially primed to learn language. Second language acquisition, including the nuances of grammar and pronunciation, appear almost effortless in early childhood.

Adults who attempt to learn a second language must put forth considerably more effort, but the consequences of not learning a second language earlier in life are reversible.

Risk Factors That Disrupt Brain Development

Neglect

To understand the impact of neglect on brain development, it is helpful to first examine the converse: *Attachment* describes the deep emotional bond that forms with primary caregivers in the first years of life. The warm and consistent patterns of reciprocal social interactions that occur within these nurturing relationships have been characterized as “the engines of development” by psychologist Urie Bronfenbrenner. Neuroscientists now agree that the “serve-and-return” communication or responsive caregiving that occurs in early childhood shapes brain development across all domains of functioning by building neural networks that dictate how the brain will interact with other people and their environment—these networks are foundational to relationships and learning. Attachment falls somewhere along the spectrum between a sensitive and critical period for development, depending on individual resiliency and contextual affordances.

What happens if secure attachments do not form in the first few years of life? Children who endure chronic neglect are at profound risk for later emotional and psychological impairment. Even physical and cognitive development can be stunted. Brain scans performed with neglected children adopted from institution-like orphanages indicated that brain architecture was underdeveloped compared to typically developing children but improved after children were placed in nurturing homes. Those who were adopted in infancy and early toddlerhood had brain scans nearly identical to typically developing children years later. Institutionalized children who were adopted after experiencing years of neglect had brain scans that indicated improvements along with enduring and irreversible impairments in brain function.

Chronic Stress

Early childhood is stressful. Learning how to take turns and how to separate from family members to enter a new classroom represent normative yet stressful experiences. Chronic stress, however, is pervasive, recurrent, acute, and uncontrollable. Examples of chronic stress include living in poverty, physical and emotional abuse or neglect, and living through the experience and aftermath of natural disaster or war. Because early childhood is characterized by brain plasticity, neural networks are wired based on experience. Children who endure chronic stress build and strengthen connections responsible for fear, anxiety, and fight-or-flight response systems compared to neural connections that promote complex reasoning and emotion regulation. The consequence of this overwiring for a stress response system is that the brain then reacts with increased fear, anxiety, and impulsivity in response to minimally stressful contexts.

Even maternal stress can impact fetal development of emotion regulation. For example, babies born in New York City shortly after the 9/11 terrorist attacks had altered salivary cortisol levels months later. Cortisol and adrenaline are hormones released in response to stress under normal circumstances. However, chronically elevated stress hormones can alter genetic expression in the hippocampus, resulting in impaired memory and learning. Chronic stress increases risk for mental illness, substance abuse, diabetes, cardiovascular disease, and immune dysfunction. Taken together, chronic stress negatively impacts the brain architecture involved in emotion development with consequences for later cognitive, psychological, and physical functioning and health.

Neurotoxins

Neurotoxins are chemicals that disrupt brain development either in the womb or during early childhood development and can cause impairments in learning, memory, attention, and emotion regulation. Three categories of neurotoxins that are especially harmful include heavy metals, organophosphates, and gestational exposure to

recreational drugs. Exposure to heavy metals can disrupt the normal function of neurotransmitters and the formation of synapses. Heavy metals may be released into the environment through industrial waste, coal-fired power plants, vehicle emissions, and more. Organophosphates are released through commercial and residential pest and insect control products. Organophosphates reduce the number of and connections between neurons. Neurotoxins can be ingested, inhaled, or absorbed. For example, fish consumed from polluted waters accumulate mercury. Lead paint commonly found in older homes creates lead dust that can be inhaled or ingested. Organophosphates may be ingested through foods we eat or inhaled and absorbed through skin at parks or playgrounds. Recreational drug use during pregnancy, especially alcohol consumption in the early gestational stages—perhaps before the mother knows she is pregnant—is highly detrimental to brain development. Children with fetal alcohol spectrum disorders (FASDs) often exhibit impaired attention and memory along with poor social skills and behavioral regulation.

Foundations for Optimal Brain Development

Optimal brain development relies on nurturing, supportive relationships with consistent caregivers in environments that stimulate children's desire to play and interact socially. Back-and-forth social exchanges increase in complexity over time and, in so doing, form and strengthen neural pathways that shape brain development and the people we become.

There is no credible evidence to suggest that infant flashcards or videos and programs designed to stimulate brain development will actually promote superior brain function. Rather than attempting to speed up the process of brain development that unfolds naturally in positive environments rich with opportunities for social interaction, efforts should be geared toward minimizing risk factors along with making informed choices about healthful nutrition, exercise, and

sleep. Early childhood educators who sensitively respond to children's needs, foster close bonds with students, and provide a safe and consistent social environment in which children are encouraged to play, explore, discover, and be creative have all the key ingredients in place for promoting optimal brain development. Indeed, positive relationships with teachers can protect the young brain and mitigate the negative impacts of neglect or chronic stress.

BREASTFEEDING

The term *breastfeeding* refers to the feeding of a mother's breast milk to a child by the breast itself; its definition can be expanded to include feeding using expressed (pumped) breast milk. Breastfeeding has been noted as the preferred feeding method for infants. This entry provides an overview of the relevant research on breastfeeding and discusses recommendations for encouraging breastfeeding and supporting mothers in their efforts to begin and continue breastfeeding.

Research

Breastfeeding has been the subject of much research interest. Various studies have reported health benefits for both the child and the mother. Babies who are breastfed receive antibodies from the breast milk. They are less likely to get ear infections, stomach viruses, respiratory infections, asthma, obesity, and type 1 and type 2 diabetes; they have a lower risk for SIDS (sudden infant death syndrome). Mothers receive benefits as well. Lower risk for type 2 diabetes, breast cancer, ovarian cancer, and postpartum depression are all related to breastfeeding.

Although benefits are reported, barriers to breastfeeding exist. Lack of knowledge regarding the specific benefits of breastfeeding and risks of not breastfeeding, along with uncertainty over how to initiate breastfeeding, have been found to reduce the likelihood that breastfeeding will be started or continued once difficulties ensue. Negative attitudes from family and friends and embarrassment have been reported as barriers to breastfeeding. Employment and child care have also been shown to be barriers to breastfeeding. Although federal legislation (e.g., Section 7 of the Fair Labor Standards Act) requires reasonable unpaid break time for an employee to express breast milk in a private location, not a bathroom, the employer is not required to do so if the employer has fewer than 50 employees and allowing breaks would create an undue hardship. Given this, many women may discontinue breastfeeding. Finding child care close to place of employment has also been reported to be a barrier, as have the feeding practices of child care providers.

Recommendations

The American Academy of Pediatrics recommends that infants be breastfed exclusively for the first 6 months of life and that breastfeeding continue with appropriate solid foods for at least the first year. *Healthy People 2020*, a publication of the U.S. Department of Health and Human Services, includes goals to increase the number of mothers who initiate breastfeeding, who breastfeed until 6 months, and who breastfeed until 12 months. Various other agencies and organizations (e.g., the American Dietetic Association [now the Academy of Nutrition and Dietetics], the American Public Health Association) have recognized the importance of breastfeeding and its impact on healthy infant development. Each provides statements of support and recommendations related to its initial implementation and continuation.

Because so many mothers are in the paid workforce, many infants are cared for by someone else. Child care personnel are in an ideal place to

encourage and support a mother in breastfeeding. The American Academy of Pediatrics and the American Public Health Association published *Caring for Our Children: National Health and Safety Performance Standards; Guidelines for Early Care and Education Programs*. Included within the guidelines are recommendations that child care facilities encourage and support breastfeeding. Establishing designated places for breastfeeding mothers to come to the child care center during their break times or lunch time to breastfeed their infants is recommended. Also suggested within the guidelines is the need for a private area with an electrical outlet (not a bathroom) so that mothers have reasonable accommodations to pump breast milk. Teaching caregivers to support and advocate for breastfeeding and implementing policies and procedures for handling breast milk safely are advocated.

BUILD INITIATIVE

The BUILD Initiative supports state and community leaders who set policies, provide services, and advocate for children from birth to age 5 years. BUILD partners with leaders working in early learning; health, mental health, and nutrition; and family support and engagement. The organization provides guidance, leadership training, and capacity building. Its cross-systems approach is intended to support families so that children can reach critical health and well-being benchmarks that foster kindergarten readiness and proficiency in reading and math skills and that generally promote thriving children.

BUILD also acts as a network that convenes state and community leaders, online and in-person, to share best practices, resources, and strategies, with a focus on integrating family and child-serving systems and advancing quality and racial equity. BUILD provides customized technical assistance that is designed to meet the unique needs of states and communities. It works intensively with 11 state partners—Arizona, the District of Columbia, Georgia, Illinois, Michigan, New Jersey, New York, Ohio, Pennsylvania, South Carolina, and Washington—and continues to grow an active learning community around the United States by engaging dozens of other states in conferences, webinars, learning tables, and other work.

The Early Childhood Funders' Collaborative (ECFC) created the BUILD Initiative in 2002. Through foundation members' grantmaking experiences, the ECFC recognized that programs, policies, and services being administered for young children and their families during the early 2000s often operated in isolation, at cross purposes, and without adequate resources to meet critical needs. In response, the ECFC designed the BUILD Initiative to foster greater coordination and increased comprehensiveness of programs, services, and policies for young children.

Increasing evidence from brain science underscores that the first five years of a child's life set the foundation for all future growth and development.

Investments in early childhood promote improved health, school readiness, and ultimately, the ability to be a part of an educated workforce critical to any country's future prosperity.

BUILD helps states develop early childhood systems that support quality and works with them to plan and implement effective quality rating and improvement systems (QRISs). BUILD also supports programs and services for children in prekindergarten to Grade 3 and efforts to strengthen the alignment of early childhood programs with K–12 schooling. Its work with state leaders particularly focuses on early learning; family support and engagement; early intervention and services for children with special needs; and children's health, mental health, and nutrition.

Although BUILD's primary focus is on the state level, since the launch of the federal Race to the Top—Early Learning Challenge in 2011, BUILD has also placed great emphasis on maximizing federal initiatives. The Early Learning Challenge (ELC) has provided grants to states to help them improve early learning and development programs for children from birth to age 5. BUILD, with many colleague organizations, supported dozens of states as they created systems plans for their ELC applications. By the end of 2013, there were three rounds of ELC funding and 20 states received grants totaling over \$1 billion. BUILD is now supporting those grantee states to effectively implement the plans and to document the efforts so that all states can benefit from the innovations and lessons learned in the grantee states. BUILD is similarly supporting states working on Early Head Start–Child Care Partnerships, preschool development, and other federal initiatives.

According to BUILD leaders, a key to building a comprehensive and equitable statewide early childhood system is developing and supporting a local infrastructure that can adapt and direct systems-building efforts to the needs and situations of young children and families in diverse geographic areas. An approach that is both statewide and community-based allows for two-way communication and learning, local buy-in, and state supports for local partnerships. BUILD is eager to increase its

ability to support robust state and local approaches to improving outcomes for the youngest children, especially those with the highest needs.

Today, a child's race/ethnicity and where he or she lives predicts the likelihood of that child's healthy development and success in school and life. In its statement *Racial Equity: Our Point of View*, the BUILD Initiative (n.d.) asserts that to address these disparities,

systems-building work at all levels can be neither "colorblind" nor passive. It must intentionally level the playing field in terms of power so that public action, allocation of resources, and oversight are shared responsibilities of a representative leadership. All actions need to be assessed to ensure impact is equitable for children and families of diverse racial, ethnic, cultural, and linguistic backgrounds and for families of diverse socio-economic statuses.

BUILD's learning community serves dozens of states, at varying levels of intensity and depth. BUILD offers "just-in-time" technical assistance. It also provides ongoing learning opportunities that bring state leaders, national content experts, federal leaders, and funders together to support systemic change.

A wide variety of events—such as conferences, topical meetings, webinars, and learning tables—are scheduled each year. As a result, the BUILD partner states, and other states working on early childhood systems, have the opportunity to

- raise issues that present the biggest challenges to success,
- learn in detail from other states engaged in similar work,
- draw on top expertise in the early childhood field, and
- foster collaborative partnerships that enhance their work in both policy and practice.

BUILD's QRIS National Learning Network brings together state implementers, technical assistance providers, and national research organizations

to advance quality rating and improvement systems in ways that truly meet the needs of our most at-risk child and family populations. Through the learning community BUILD is able to work with states to articulate cutting-edge issues and questions, support pilot projects that experiment with new strategies, and create practical tools to support state efforts.

BUSINESS PARTNERSHIPS

Business leaders have emerged as major actors in the growing support for early childhood services worldwide. A growing body of rigorous research has shown that the first few years of life are crucial for helping children become productive employees and good citizens. Since executives have realized that early childhood programs are essential for workforce development and economic prosperity, they have taken actions ranging from supporting local services to directly advocating for policy change. This entry briefly traces this background and provides examples of current actions.

Background

Business leaders are driven by data and accustomed to making decisions based on information that affects their company. Their actions in support of early childhood development have been spurred by research that conveys the impacts of early childhood programs on preparing children for successful adulthood. These programs cover a wide range of areas, including education, nutrition, health, and parental supports. The combination of increased understanding of the importance of early brain development, along with a growing body of rigorous economic data on program outcomes, has created a compelling case for action. Because of these data, executives are taking prominent roles in changing public and private systems helping young children and their families.

One key factor in this transformation was the change over the first decade of this century from viewing early learning services as child care that enables parents to work, to seeing these services as education that lays the essential foundation for later academic achievement. A major driver of this change was the national prekindergarten advocacy campaign launched by the Pew Charitable Trusts that lasted from 2001 to 2011. A second significant turning point was the publication in 2003 of a seminal article by Arthur Rolnick and Rob Grunewald of the Minneapolis Federal Reserve Bank, which

re-characterized early education again—as an economic development strategy comparable to, but even more effective than, traditional job creation projects.

These developments helped transform the vision of early childhood programs from just another worthy charity to a crucial educational and economic development strategy that can boost a community's quality of life, contribute to a well-skilled workforce, and expand economic opportunity. All of these factors have led business leaders across countries, industrial sectors, and company sizes to realize that providing young children with a nurturing environment is a business concern. This realization has spurred executives to devote much more time, attention, and resources to early childhood and to take on a wide variety of roles.

Partnership Models

Business partnerships to support early childhood can take many forms. They include the following.

- Business groups that have taken on early childhood as a key concern. ReadyNation is a national membership organization with 1,100 executives, including current and former Fortune 500 chief executive officers (CEOs), who advocate for improving the economy and business climate through effective investments in children and youth at the state, national, and international levels. At the state level, the Ohio Business Roundtable and the Business Council of Alabama both count early education as one of their top policy priorities.
- Policy advisory bodies that are either dedicated to early childhood or include it in their scope. Pennsylvania's Early Learning Investment Commission consists of 76 executives and civic leaders, appointed by the governor, who are charged with spreading the message of the importance of early childhood.
- Public-private entities that raise and administer funds for early learning programs. Nebraska's Sixpence program has raised a significant endowment for early childhood from the public and

private sectors. A coalition of major Minnesota business leaders, from companies such as 3M, General Mills, and Ecolab, raised funds to research, design, and launch an early learning scholarship program, along with a quality rating system called Parent Aware. That group is now driving a major new service delivery program in the state covering home visiting and early learning programs, driven by parent choice.

- Early childhood coalitions with business members that effect change at the local, state, or national levels. Many business leaders participate in California's First 5 commissions, Virginia's Smart Beginnings councils, and Michigan's Great Start coalitions.

The groups, as well as individual business champions, are taking a variety of actions to effect change, from the local to the international levels. These fall into three main categories:

1. Actions to support community-based, direct service projects
2. Actions to use their public positions and status as unexpected champions to call attention to the importance of early childhood
3. Actions to effect widespread policy change, at the local, state, national, or international levels

Community Actions

While charitable giving has been a traditional corporate role, changes are occurring that reflect a deeper understanding of early childhood and a more expansive view of the supports executives can provide. For example, companies with a high demand for technically trained employees, such as Northrop Grumman and IBM, are supporting projects aimed at promoting early interest in science, technology, engineering, and math (STEM) education.

A new type of financial contribution comes not from a company's charitable arm but from its investment portfolio. Pay for success contracts (otherwise known as social impact bonds) create a funding stream for specific early intervention

programs that have rigorous data showing their impact on important outcomes. The savings from those outcomes are then returned to continue the services and pay off the initial investors. For example, the first early childhood pay for success contract in the United States, funded by private capital from Goldman Sachs and J. B. Pritzker, invests in prekindergarten for disadvantaged children. These services are provided by the Granite School District near Salt Lake City, with the expectation that the program will generate savings to the school district by reducing special education costs. If the outcomes are as expected, the savings would be used to repay the investors and the school district in order to continue providing pre-K services.

Public Education

The past decade has seen a dramatic change in the number and prominence of executives who are speaking out on the importance of early childhood as a business issue. ReadyNation's 1,100 business members, including current and former Fortune 500 CEOs, regularly speak to key audiences at the local, state, and national levels. Over 2013–2014, its members appeared in the media more than 400 times, either as part of news articles or through writing op-eds, mostly on early childhood. In March 2015, ReadyNation released an open letter to the United Nations leadership, signed by more than 50 executives from several countries, recommending that early childhood be a priority goal in its sustainable development goals. Other companies have released important reports that put their clout behind the idea of early childhood as a key economic concern. For example, the Australian arm of accounting firm PwC created, pro bono, a major report called "Putting a Value on Early Care and Education in Australia."

Policy Advocacy

Improving the lives of whole generations of young children, worldwide, requires government action. The most powerful role business leaders

can play is to influence the public funding streams and regulations that are necessary to provide the health, nutrition, parent help, education, and other supports that young children need to thrive. In 2013–2014, ReadyNation members had more than 400 direct communications with U.S. policy makers, to support expanded funding of, quality of, or access to early childhood services at the state or national levels.

Several large companies have taken on multidimensional roles that encompass many of these actions and that illustrate their deep commitment to this issue:

- PNC Financial Services Group in the United States was one of the early pioneers in this era, with its Grow Up Great initiative that encompasses employee volunteerism, parent education, local community donations, and advocacy at the state and national levels.
- Denmark-based LEGO Foundation has a five-part initiative addressing children from birth to age 12 called “Play-Based Learning, Sparking a Global Dialogue, Re-imagine Learning, Capital of Children” (which mobilizes the whole city of Billund, Denmark, to focus on children) and local LEGO employee engagement.
- Global accounting firm KPMG created Family for Literacy, which has donated more than two million books through 90 offices worldwide, including Mexico, India, Nigeria, South Africa, Zambia, and the United States. Its executives are also key advocates for early childhood policy in two states.
- Pharmaceutical company Eli Lilly pushed local government in Indianapolis, Indiana, to create a new prekindergarten program to improve the quality of life and attract more scientists with young families. Robert Smith, president of the Lilly Foundation, said in the *Indianapolis Star*, “We can no longer afford this small-ball politics that has defined how we address problems. The message our CEO is sending is that this is critical to the future of our community” (Tully, 2014). The company has also given multimillion dollar donations to support an array of local early learning programs.

These diverse and deep partnerships illustrate that early childhood education has become a significant issue for business leaders who focus not only on the workforce of today but also on the customers, employees, and citizens they need for the future.

C

CARING

Caring is the active appreciation of other persons and the willingness to treat them with consideration and respect. Caring is central to early childhood education because it communicates to children that they are valuable as persons: that their feelings, ideas, and preferences are worthy. When a child lives in an environment of caring, she builds an attachment of trust with her caregivers, with her surroundings, and with her own inclinations.

At the core of caring is the teacher's ability to see that a child is a person. This very young person cannot take care of his own daily needs independently, but he does have personal preferences, individual needs, and intrinsic desires. The caring teacher respects the child's every effort to learn. Good child care thus consists of regular, beneficial practices such as diapering, feeding, napping, and playing (all of which communicate care), as well as the nurturing of a child's special interests, talents, and temperaments.

To be caring does not mean to allow children to do whatever they want, however. Caring teachers also kindly insist that the children do their personal best every day. Caregivers remind and redirect children to treat others in ways that are respectful. Through consistent and predictable boundaries, through learning the arts of sharing and compromise, and through enjoyable working

and playing with others, children are taught to be caring: to respect other people, to respect materials and equipment, and to accept and moderate their feelings and actions.

Each interaction with children is an opportunity to show caring. Even the wink of the eye or a connecting smile can communicate care to a child. Likewise, providing regularly for a child's needs to eat, talk, run, play, sleep, and wonder teaches a child that his or her environment is safe and he or she can reach out to learn new things.

Caring teachers show children understanding, compassion, and empathy. When children know that their feelings, ideas, and actions matter, they are inspired to put forth their best effort. Therefore, children who have felt caring trust themselves and their caregivers; they try harder and persevere longer. Also, children who feel acceptance are themselves more accepting of differences. They show greater self-regulation and tend to treat others with understanding and kindness. Homes and classrooms that are full of care are permeated with purposeful activity, negotiated roles and rules, and recognition of the worth of each person.

Care as Respect for All

When a caregiver communicates respect to a child, she is showing the child that she believes the child and his or her activities are interesting and valuable. As a result, the child feels admired and worthy. The child learns to believe in the

usefulness of his or her actions and feels free to explore and try out new ideas.

There are many ways to communicate respect to a child. One way is to stop and listen: What is the child saying and what does he or she mean? When a caregiver takes the time to listen with interest, the child feels affirmed and respected. Active listening (rephrasing what the student says) and questioning (delving deeper into the student's comment or activity) lengthen the conversation in ways that extend the student's learning. For instance, when a child is telling about a special occasion at home, talking excitedly and with disconnected details, a caring listener continues to make eye contact with the child, nod, and make sense of the details that are clear. As the child winds down, the caregiver might reply, "What an exciting time you had!" With older children, a caregiver might listen for ideas and events that the child finds interesting and later plan play activities that build on those interests.

Another way to communicate respect to a child is to use respectful, reciprocal language. Just because children are younger and less independent than adults does not mean that they need loud, harsh, or demeaning directions or redirections. Simple language such as "It's time to clean up now" and redirections such as "We're putting away our toys now" are more respectful than tough words or unsympathetic orders.

It is particularly important to use respectful language when a child has made a mistake or is in danger. For example, if a child has taken off his or her shoes and is proceeding to walk into broken glass, a caregiver who responds, "Stop! Your feet are walking on sharps! You will cut your feet and it will hurt!" shows respect for the child's activity but alarm for the risk of injury. On the other hand, a caregiver who urges "Stop! I've told you a hundred times to keep your shoes on! Why don't you ever do what I say? If you get cut, it will be your own fault!" is blaming the child without giving him or her enough information to know why he or she has made a bad decision.

Using affirming language is another way to communicate respect and caring to young children.

Just as the listening teacher communicates "I am interested in your story," the affirming teacher communicates "I am interested in your work." As young children busily move from place to place in the home or classroom, an affirming caregiver notices their activities and makes general, supportive comments during the work. For example, a child who is building a block tower can be inspired by the caregiver's counting as each block is added. A child who is feeding the baby doll hears "I see that your baby is hungry again" as recognition of a job well chosen. Occasional affirmation and recognition fuel the children's energy to be and stay engaged.

Using respectful language and a caring attitude has reciprocal and multiplicative benefits for the social atmosphere. Because young children emulate the words spoken in their environments, they pick up the language of caring and respect and use it with their peers and their caregivers. Thus, the environment is characterized by a language of mutual respect, creating a climate of acceptance.

Care as Understanding, Compassion, and Empathy

Caring teachers are advocates for their students. They understand that, deep down, the child is trying as hard as he or she can and wants to do well. Excellent caregivers perceive children as capable and assume that children's behavior is essentially reasonable. When the child is acting unreasonably, the caregiver searches for an explanation either in the child or in the environment for the misbehavior. Equipped with this outlook, the teacher supports the child's attempts to make sense of the environment and has patience, compassion, and empathy when the child repeats unusual, undesired, or unproductive activity.

Caring teachers strive to understand their students and are always learning about them. They take note of individual children's behavior and motivations and weave together the observations into a coherent portrait. They communicate this portrait to others with appreciation and seek advice about how to best meet the child's needs.

Understanding young children is not an easy or direct task; it requires study, close observation, and reflection. For example, the caring teacher listens closely to the cries of the infant to interpret if the child is wet, tired, hungry, or hurt. Likewise, the caring parent watches the child's attempts to mix mud and water and recognizes from his or her labored breathing and focused attention that his or her small hands are working hard to squeeze the material.

The caring teacher empathizes with his or her students. He or she celebrates with them when they succeed, and when they do not, he or she encourages them to attempt alternate means. The early childhood caregiver recognizes the challenges in simple tasks and takes the child's point of view as he or she encourages and teaches the child. The empathetic caregiver knows when the environment is not interesting to the child and takes steps to improve it. The caring parent knows that the child is bored and wants to play with something in the kitchen, and provides a set of spoons and sauce pans so the child can make sound. If pots and pans are too noisy for the parent, he or she provides a cup of flour and a sifter so the child can sit and sift.

Care as an Ethic of Helping

Young children need much assistance in their daily lives. An early childhood caregiver provides for young children's basic survival needs (food, water, oxygen, sleep) as well as their safety (shelter, security) and psychological (love, acceptance, belonging) needs. A young child thrives when his or her needs are met as soon as possible. However, because young children lack experience and perspective, they do not always know what they need; therefore, the caregiver may not be certain how to respond helpfully or promptly. In addition, a caregiver's time and focus may be divided between the young child and a host of other duties, with immediate satisfaction of a child's needs difficult to supply.

Helping is caring when the child understands that the caregiver is acting in the child's best interest. A child may fuss when he or she is placed on

the changing table but become happier when released with a dry diaper. The child gradually comes to know that this ritual is in his or her best interest and that the diaper-changer cares about him or her. A child may balk at sharing the blocks with a peer; the early childhood teacher helps the children negotiate an agreement; the child becomes grateful for the solution. Responsive, collaborative classrooms are ones where students and teachers help each other.

Care as the Commitment to Teach All Children

Today's child care homes and centers care for children from many backgrounds and circumstances. Early childhood teachers care for each child regardless of his or her abilities, ethnicities, religions, heritage, or temperament. They give each child what he or she needs and ensures that all children receive a high quality of care. The climate of acceptance and the resulting caring social atmosphere provides a safe space for children to consider and accept themselves as individuals.

Teachers who connect with every student every day model an acceptance of difference that students can emulate. Early childhood caregivers circulate throughout the learning space to talk with each and every individual about his or her activity. Children who are more active or less appealing to the eye are treated with respect. The caring teacher safeguards against the exclusion of any child; if a child is told he or she can't play, the teacher moves in to help children better understand the underlying situation and to help them negotiate a solution.

During group activities, teachers encourage the participation of every student. With patient energy, caregivers solicit ideas, insist on turn-taking, and listen to each child's words. They encourage all children to use prosocial behaviors for the good of the group. The teacher's stamina for including everyone in the life of the classroom is the student's cue for his or her own acceptance of difference.

Early childhood educators know that cultural differences and mismatch can lead to marginalization

of students who are “not like us.” Teachers acknowledge that they are cultural beings with value-laden theories about themselves and others. A caring teacher examines his or her own predispositions with sincerity and allows for others’ beliefs and values to be expressed, as long as the well-being of the community is not compromised.

Caring teachers do not tolerate blaming, scapegoating, or apathy by children or colleagues. Early childhood caregivers ensure that all students are progressing in their development and expect for all children to do their best every day. Through communicating high expectations, the friendly, warm teacher sees to it that all students advance. Caring teachers build relationships that bind together the group so that it can support and encourage each individual.

CARING COMMUNITIES

Every child deserves access to high-quality early childhood education, as President Barack Obama articulated in his 2015 State of the Union address.

A critical component of high-quality early education is an emphasis on social and emotional development. A growing body of research documents the importance of social and emotional skills for short- and long-term academic success. Many teachers, however, lack strategies to promote these skills effectively, which likely contributes to the high expulsion rate of children in preschool nationwide. Effectively promoting social and emotional skills requires the development of caring communities. Numerous intervention programs have emerged focusing on one or more of the aspects of establishing caring communities in early childhood classrooms. Caring communities are those in which educators (1) foster secure relationships with children, (2) model strong social and emotional skills, (3) intentionally teach social and emotional skills and provide opportunities for children to practice and apply these skills, and (4) engage families in social and emotional learning.

Caring communities not only support social and emotional development, but they also lay a

Figure 1 Developing Caring Communities in Early Childhood Education

critical foundation for children's social and academic success in early childhood and beyond (see Figure 1). This entry first provides an overview of the importance of developing social and emotional skills through establishing caring communities in early childhood settings. It then gives an overview of the theoretical foundations supporting the framework for caring communities and examples of intervention programs targeting the development of caring communities. Finally, it describes how caring communities are measured.

Developing Social and Emotional Skills During Early Childhood

Creating caring communities in early childhood is essential to effectively promote children's social and emotional development. Importantly, social and emotional skills have been linked to integral learning processes and a range of achievement outcomes. For example, studies have found significant associations between children's social and emotional skills and positive relationships as well as early literacy and math skills, even after controlling for income and IQ. When surveyed, early childhood educators have identified children's social and emotional skills as critical for classroom success and necessary for a successful transition to kindergarten. Children who lack the social and emotional skills critical for classroom success are at risk for achievement gaps that can persist throughout their schooling.

Early childhood education settings are an ideal place for interventions aimed at improving social and emotional skills. During early childhood, children's vocabulary (including emotion-related vocabulary) increases substantially, children begin understanding the causes of emotions, and there is significant brain development in the prefrontal cortex, an area associated with the ability to develop and employ emotion regulation strategies. Promoting caring communities in early childhood settings helps ensure that children have the support they need during a key developmental period of growth in social and emotional skills.

Theoretical Foundations of Caring Communities

The conceptualization of caring communities presented in this entry is informed by numerous theoretical foundations, including Urie Bronfenbrenner's bioecological model of human development, John Bowlby's work on attachment theory, Albert Bandura's social learning theory, and research on emotional intelligence conducted by Marc Brackett and colleagues. Together, these theories address the context in which learning occurs (classrooms, homes), the structure of that learning (e.g., attachment practices, modeling), and the content of learning (social and emotional skills and knowledge).

According to the bioecological model of human development, child development occurs within a system of multiple influences with the child at the center (the microsystem). The level surrounding the child (the mesosystem) represents the environment and relationships a child has at home and at school. Additional levels of the model include the exosystem (e.g., political system), macrosystem (e.g., overarching societal beliefs), and chronosystem (e.g., time). Being at the level most proximal to the child, the relationships that a child has at home and school interact to shape multiple domains of development, including social and emotional development. For example, a study of infants, toddlers, and preschoolers found that having a secure attachment relationship with their mothers predicted higher levels of teacher involvement than having other attachment styles (e.g., avoidant or ambivalent). Another study found that connectedness between 5-year-olds and their mothers significantly predicted children's mutual friendships and peer acceptance at school. These studies highlight the interaction between home and school influences, supporting the inclusion of both in establishing caring communities that effectively support children's social and emotional growth.

The importance of secure relationships as part of establishing caring communities is supported further by attachment theory. This theory posits that the presence of a secure relationship with at least one parent or caregiver is foundational to social and emotional development and the ability

to create and maintain positive relationships. A secure attachment relationship is one in which a caregiver consistently provides sensitive and responsive care while adapting care to meet the needs of each child. There is a growing body of evidence showing that warm relationships with early childhood teachers predict children's social and emotional skill development, positive relationships with peers, engagement in learning, and academic achievement. Early childhood educators who promote secure relationships create caring communities, laying an important foundation of trust between themselves and the children in their classrooms.

By demonstrating behaviors and styles of interacting with others, trusted adults act as role models for children, according to social learning theory. Adults who model social and emotional skills can demonstrate to children effective strategies for managing emotions. By imitating the strategies they observe, children are able to further develop their social and emotional skills. Research documents that an educator's ability to model strong social and emotional skills is a critical component of interventions aimed at promoting these skills in children. Parents and educators also can intentionally teach these skills and give children routine opportunities to apply them in school and at home.

In addition to modeling, parents and educators play an integral role in intentionally teaching these social and emotional skills and helping children apply them in classroom settings as proposed by Marc Brackett, Susan Rivers, and colleagues in the achievement model of emotional intelligence. This model, developed from the theoretical and empirical work on emotional intelligence by Jack Mayer and Peter Salovey, Susanne Denham's research on emotional development, and Carolyn Saarni's work in emotional competence, specifies that children will be most effective in social relationships as well as academically when they are given opportunities to practice and develop social and emotional skills and apply them in their daily lives. The model further specifies that direct instruction of social and emotional skills is most

effective when promoted in the context of caring communities.

Creating Caring Communities in Early Childhood

The Collaborative for Academic, Social, and Emotional Learning (CASEL), a nationally recognized organization aimed at promoting social, emotional, and academic competence at all grade levels, has identified numerous early childhood interventions that have been shown to improve social and emotional outcomes through targeting the components of a caring community. Few of these programs, however, target all four dimensions critical to effectively establish caring communities. *AI's Pals*, *Promoting Alternate Thinking Strategies (PATHS)*, and *I Can Problem Solve* are examples of programs that use classroom lessons to teach explicit instruction of children's social and emotional skill development. *The HighScope Educational Approach for Preschool* and *Tools of the Mind* are examples of programs that focus on improving teachers' instructional practices related to social and emotional learning.

Preschool RULER, which was developed at the Yale Center for Emotional Intelligence and adapted in 2012 from a CASEL-select program, the RULER Approach, is an example of a program that targets all four components of caring communities. Drawing from the theories described in previous sections, Preschool RULER provides tools and a shared language that enable educators and family members to practice and model their own social and emotional skills as well as embed the teaching and practice of these skills throughout the day in early childhood settings. Developing children's social and emotional skills is targeted through a focus on five key social and emotional skills (recognizing, understanding, labeling, expressing, and regulating emotions) that are remembered through the acronym RULER, which provides the name for the approach. Preliminary findings from a pilot test found that children at a school implementing Preschool RULER exhibited

greater gains on a direct measure of social and emotional skills across the school year than children at a control site.

Measuring Caring Communities

Effectively assessing all of the components of a caring community requires a multilevel assessment plan using a combination of direct assessments, surveys, and observational measures to assess children's social and emotional skills, relationship quality between children and caregivers (educators and parents), instructional practices related to social and emotional skills, and family involvement. Currently, the most comprehensive and widely used measure assessing caring communities is the Classroom Assessment Scoring System (CLASS), which was developed by Robert Pianta and his colleagues at the Curry School of Education at the University of Virginia. The CLASS measures the quality of the social, emotional, and instructional interactions within a classroom. The social and emotional climate in early childhood settings is determined by the quality of interactions between and among educators and children in a classroom, with classrooms demonstrating high-quality and supportive relationships being indicative of a caring community. The social and emotional climate of classrooms is a critical factor for learning, as evidenced by the positive associations between classroom climate, student behavior, and academic engagement. A positive classroom climate has been associated with decreased internalizing behaviors and increases in child autonomy in kindergarten and first grade as well as greater increases in preschoolers' social and emotional skills. Research also has consistently demonstrated that a positive classroom climate predicts child literacy skills in preschool and first grade. Moreover, young children with significant behavior and emotional problems fare especially well in classrooms with a positive climate.

Conclusion

Caring communities are foundational to children's social and emotional growth and development.

There are four key components involved in creating caring communities; however, intervention programs rarely provide the support educators need to effectively promote all of these aspects. During the early childhood years, creating caring communities can help ensure that children develop the critical social and emotional skills they need for social and academic success.

CENTER FOR APPLIED RESEARCH

The Center for Applied Research was launched by the National Association for the Education of Young Children (NAEYC) in fall 2010. Its purpose is twofold: (1) to ensure that the work of NAEYC is based on the best available research, and (2) to communicate research with early childhood professionals engaged in practice and policy work. This entry describes the history and role of the center.

Research has long been a critical component of NAEYC's accreditation standards as well as its position on developmentally appropriate practice (DAP) and its journal, *Young Children*. Although research has been present in the work of NAEYC since the organization's earliest days, by the early 2000s there was growing awareness that its importance needed to be noted, especially within the

context of research-practice-policy interactions. NAEYC took an initial step in forming the Office for Applied Research in the mid-2000s. In 2007, the NAEYC Office for Applied Research and the Society for Research in Child Development (SRCD) hosted the Wingspread Conference, "Using Research to Improve Outcomes for Young Children: A Call for Action." One conclusion from this summit of early childhood education experts—that there was critical need to effectively translate research into practice—was the primary impetus for NAEYC's decision to launch the Center for Applied Research, specifically dedicated to ensuring that its work was research-based.

The Center for Applied Research ensures that the work of NAEYC is consistent with research on child development and early childhood education. It does so by working within NAEYC organizationally, as well as through NAEYC to reach early childhood professionals in research, practice, and policy contexts. As such, the center serves a unique, dual, role. While it pursues original research, its primary focus is on center-based early care and education centers that are the focus of NAEYC'S work, especially early childhood programs that pursue NAEYC accreditation and institutes of higher education that pursue accreditation or recognition by NAEYC in preparing early educators. For example, the center analyzes data from NAEYC accreditation systems to identify trends in early childhood education programs. These efforts are directed specifically at NAEYC activities. In addition, within NAEYC, the center acts as a hub to ensure that NAEYC position statements and accreditation standards reflect the current state of research. In this way the center links the work of NAEYC with research and practice in the field.

The Center for Applied Research also works beyond the organizational context in efforts to translate research to practice and policy. Externally, one of the center's primary goals is to effectively communicate research in early childhood development and education. This communication includes presenting and explaining research findings to practitioners and policy makers, as well as talking to researchers about gaps in current knowledge.

Some of the center's communication efforts are overt—they take the shape of blog posts, articles, conference presentations, or press and media interviews. Other efforts are less overt but are integrated into NAEYC accreditation standards and NAEYC policy work. The center is intended to be dynamic, to focus on issues as they emerge as well as anticipate future directions. The center has focused longer forms of communication on the assessment of young children and implementation of the Common Core State Standards Initiative.

While research has been part of the work of NAEYC since its inception, the growth of research and public interest in early childhood education led to the formation of the Center for Applied Research. Likewise, current and future work of the center will be driven by, while also contributing to, emergent trends in research and practice in early childhood education.

CENTER-BASED CARE

Center-based child care provides families with full-time and part-time care in settings outside of the home. Child Care Aware of America reported in 2013 that nearly 11 million children younger than age 5 are in some type of child care center setting for an average of 35 hours each week. Center-based early care and education centers can be described in terms of enrollment size, ages of children served, hours of operation, services provided, auspice and sponsorship, and revenue sources. In addition to these structural features, families can use quality indicators of licensing, participation in quality improvement systems, and accreditation status to make informed decisions regarding a particular child care center. Quality elements, including skilled teachers, high staff-to-child ratios, appropriate curricula, and active child engagement in activities, have also been associated with long-term academic and social outcomes for children enrolled in center-based care. This entry first discusses the differences in types of center-based programs and sponsorship. It then discusses how the programs are funded, cost and quality factors, and the program outcomes associated with center-based care.

The National Survey of Early Care and Education (NSECE) included 129,000 center-based programs serving almost 7 million children birth through 5 years who were not yet in kindergarten. NSECE found that enrollment in programs varies nationally, with about 25% of the programs serving 25 or fewer children and about 33% serving more than 75 children. Three in 10 programs offer fewer than 30 hours per week of care, suggesting that program goals are not designed to support parental employment but may provide socialization or early learning opportunities for children whose parents may or may not be in the workforce.

Center-based child care programs may serve children birth to age 3 years, ages 3 through 5 years, or who are school age. Some programs serve only children 3 through 5 years of age, whereas other programs serve children in all three age groups.

According to the 2014 NSECE survey, about 52% of early childhood programs are not-for-profit, about 32% are for-profit, and the remaining programs are run by local, state, or federal government agencies. Regardless of program type or auspice, tuition is paid by parents in 68% of the programs; public funds from state, local, or federal sources are received by about 73% of centers. Fifty-five percent of children in center-based programs attend programs that are not sponsored by a public school district and do not receive Head Start or public prekindergarten funds.

Program Types

Center-based child care differs based on hours of operation, services provided, and curricular models implemented. Programs operating less than 30 hours per week include faith-based preschools, parent cooperative programs, and community-based preschools. Some Head Start programs and some state-funded prekindergarten programs also operate for less than the full day. These programs may offer extended day options to families to provide care for the full day, or working families who select these programs make alternate arrangements for child care. Full-day programs are most frequently operated by not-for-profit and for-profit organizations whose missions are to serve working families. Hours of operation frequently begin between 6 and 7 a.m. and end between 6 and 7 p.m. to accommodate parents' working hours. There is limited center-based child care for families who work evening shifts, weekends, and holidays; however, some employers, such as hospitals, may provide center-based care for their employees who need child care in the evenings, on weekends, and on holidays.

Center-based programs are often differentiated by the services they offer to children and families. For example, many publicly funded programs offer comprehensive services that include health and nutrition, social services, and family support service components to children and families. These programs may also provide transportation for children to attend the program and to parents to access services provided by the program. Not-for-profit

and for-profit centers more typically offer additional services at additional costs. Fees are charged to support program operation and may include registration, insurance, transportation, extended day, supplies, meals, and activity fees.

Curricular models also serve to distinguish center-based programs. Some programs provide developmental, choice-based curriculum options that are designed by the staff, owners, or franchise. Other programs purchase commercial curriculum packages that are used to advance academic goals or provide a framework for the school day. Still other programs use models that reflect particular theoretical or philosophical approaches such as Reggio-inspired, Montessori, HighScope, The Creative Curriculum, or Waldorf models. These curricular models require specialized staff training and development and may utilize specific materials and equipment. They are also associated with particular outcomes such as improved language and literacy, math, creative thinking, and cognitive development.

Auspice and Sponsorship

Auspice refers to a program's status as for-profit, not-for-profit, or government-run. For-profit programs include small owner-proprietor programs with a few employees and franchises or chains of child care centers. Not-for-profit programs include independent programs run by organizations that only provide early childhood programming and programs that are sponsored by umbrella organizations with broader faith-based or social service missions. Government-run programs include center-based child care that is funded by local school districts, state-funded prekindergarten programs, and Head Start programs run by human services agencies.

Sponsorship refers to additional oversight of some not-for-profit programs and those run by government agencies. According to the NSECE survey, about 30% of center-based child care programs are independent, not-for-profit centers; about 27% are for-profit independent centers; about 5% are for-profit and part of a franchise or chain; and 20% are not-for-profit sponsored

centers. Less than 15% of all programs are run by a government agency. The remaining 3% of programs were identified in the survey as “other.”

Revenue Sources and the Cost of Center-Based Care

Sources of revenue for center-based programs come primarily from the tuition and fees paid by parents. Other revenue sources include tuition paid by the state government in the form of vouchers, grants, or prekindergarten funds; local government funds; federal government funds for Head Start, Title I, and the Child and Adult Care Food Program; community organizations such as the United Way; and/or fund-raising activities. These funds may be blended or braided at the local level to more efficiently utilize resources and serve more children.

Affordability, the cost of the program or service for the family or provider, is affected by staff qualifications, provider–child ratios, and types of services provided by the program (e.g., transportation, meals, and curriculum materials). Parents report that affordability of care is their major concern in seeking child care for their children. Cost of center-based care varies by the age of the child, reflecting staff-to-child ratios that are higher for infants and lower for preschoolers. Cost is also affected by the location of the center with variations between rural, urban, and suburban areas as well as across geographic regions. For example, the average annual cost of full-time care for an infant ranges from \$5,500 in Mississippi to \$16,550 in Massachusetts. The average annual cost of full-time care for a 4-year-old in center-based care ranges from \$4,500 in Tennessee to \$12,300 in Massachusetts.

The cost of providing affordable care can be challenging for the providers who base their rates on the cost of doing business and their access to external resources (e.g., ability to seek external funding through grants and fund-raising activities, public funds, and private contributions). Salaries in child care, the highest cost for providers, are typically low, even in the highest quality, most successful programs. Approximately 80% of the cost of center-based child care is related to payroll expenses even though professionals in child care are among the

lowest paid professionals. Regulations related to adult–child ratios and class size further impact affordability in terms of the number of children who can be served and the cost to provide adequate numbers of staff at each age level, making infant care the most costly to provide and to afford.

Quality

Quality refers to the standard of excellence to which a program is held accountable. Publicly funded programs are generally of high quality; however, center-based child care programs exhibit the greatest variability in quality, resulting in large part from the different levels of regulation (e.g., licensed, voluntarily registered, religious exempt, unregulated) and staff qualifications. For those programs participating in quality improvement activities through a quality rating and improvement system (QRIS) or accreditation through the National Association for the Education of Young Children (NAEYC), quality is generally much higher, although participation in these two programs is also highly variable.

Licensing of child care centers provides assurance that the center meets minimal levels of safety, teaching standards, and curriculum. State and federal background checks of employees, minimum educational requirements, and health and safety requirements vary from state to state. Based on its review of state laws, policies, and oversight, Child Care Aware of America notes that licensing regulations for child care centers are minimal. Thirty states inspect child care centers two or more times a year; however, nine states do not require any type of inspection at least once a year.

A QRIS is provided in many states as a way to systematically assess, improve, and communicate the quality of care offered by child care centers. States differ on the type of components they include in their individual QRIS plans and in the ways they implement their systems. According to the National Child Care Information and Technical Assistance Center, QRIS is statewide if the system is open to providers in all geographic regions of the state and incorporates standards, accountability measures, program and practitioner outreach and support, financial incentives, and parent/consumer education efforts.

NAEYC accreditation is a voluntary, national system designed to improve the quality of center-based child care by developing a standard of excellence and providing tools to support programs in making quality improvements to achieve the standard. By early 2015 there were more than 6,900 NAEYC-accredited child care programs serving over 603,000 children.

Program Outcomes Associated With Center-Based Care

Effective center-based child care programs provide some combination of the following six characteristics: (1) highly skilled teachers; (2) small class sizes and high adult-to-child ratios; (3) age-appropriate curricula and stimulating materials in a safe physical setting; (4) a language-rich environment; (5) warm, responsive interactions between staff and children; and (6) high and consistent levels of child participation. The most extensive evidence for the benefits of high-quality learning environments, particularly for children from low-income families, comes from a growing number of programs that serve 3- and 4-year-olds. Evaluations have also shown positive effects of some early care and education programs that began shortly after birth (e.g., the Abecedarian Program), but fewer long-term studies of these programs have been conducted.

A variety of studies have demonstrated that participation in very high-quality, center-based early education programs enhances child cognitive and social development. For example, the National Institute of Child Health and Human Development (NICHD) report found that children who received high-quality care in the first years of life scored higher in measures of academic and cognitive achievement 10 years after leaving care. Children who spent extensive time in center-based care with larger peer groupings were more likely to display challenging behavior at age 54 months and at kindergarten age. However, children's behavior was within the typical range and a minority of children appeared to be affected. On the other hand, studies suggest that children in poor-quality care do not

fare as well and outcomes are significantly worse for children from low-income families.

CHALLENGING AND SUPPORTIVE CLIMATES

Environments that best nurture young children's development have long been considered an essential component of early childhood education. The term *climate*, when used in conjunction with learning environments for children, is inclusive of the physical, social, emotional, and cognitive setting. The learning climate results from the organization of the learning space itself, the teacher-child interactions, and the interactions between the children. A climate that is characterized as challenging and supportive is intentionally created in such a manner that children's total development will naturally be promoted. Additionally, the knowledgeable early childhood educator utilizes guidance, creates learning opportunities, and provides instruction consistent with children's current level of functioning, while also facilitating growth through intentional scaffolding. A well-structured classroom for young children is planned with the understanding that children are mentally active, capable learners; that the development of the whole child must be nurtured; and that interactions should be responsive to the unique development of each child. High-quality early childhood education programs are created, in large part, through the provision of such climates for young children. This entry discusses the components of challenging, supportive climates in terms of young children's physical, social, emotional, and cognitive development.

Physical and Social Environment

Classroom spaces for young children have historically differed from learning spaces for older children in significant ways. In the nursery school approach of years past, classrooms were divided into activity areas, facilitating children's engagement in various kinds of play. Examples of the common nursery school areas were block play, science investigations, dramatic play, and creative art. The physical environment in the nursery school was created with the understanding that children's

social development was critically important to their total learning and development. Thus, specific work/play areas were provided to facilitate meaningful social interactions among the children.

Among the many particular nursery school philosophies is the Montessori approach, developed by Italian physician Maria Montessori in the early 1900s. Montessori's approach emphasized the preparedness of the physical environment, with the goal of fostering children's independence. As dictated by this philosophy, environments that support and challenge children appropriately are arranged to encourage children to move freely from one activity to another, often choosing whether to work alone or with friends; are neat, clean, and have visible order, allowing children to access and then return materials to their places; include furniture scaled to the children's size; make available only those materials thought to be matched to children's developmental abilities; and include outdoor learning as well as experiences inside the classroom. Montessori's educational principles for young children gained popularity in the United States in the 1960s and continue to have a strong presence in the landscape of American education for our youngest learners.

Several other distinct approaches for promoting children's learning and development have been conceived throughout the history of early education and have remained as influential forces. Perhaps among the most notable, in addition to Montessori, are HighScope, Bank Street, and Waldorf schools, each of which has unique principles for classroom spaces. What is common to each of these is the notion that physical spaces for young children should be responsive to the developmental needs of children and that children's individuality should be valued and supported, even in the preparation of the classrooms. Classroom environments for young children are created with intentional thought about developmental characteristics and their implications for furniture, arrangement of space to facilitate social play as well as independence, children's work displays, and access to interesting and appropriately challenging materials.

A more recent early schooling philosophy is the Reggio Emilia approach, created several decades after the aforementioned schools. By the 1990s, the Reggio methodology had earned national and international acclaim as a model for quality early education. Developed after World War II, in the small Italian city of the same name, Reggio Emilia schools are characterized, in part, by the understanding of the environment as the “third teacher” (after the parent and the classroom teacher). The physical climate within Reggio classrooms is created with natural lighting, inclusion of plants, materials found in nature as objects for exploration, and room arrangement that invites children to thoughtfully select and pursue investigations and to create representations of their thinking. Displays in the Reggio classroom include only what is interesting and relevant to children’s study, such as photo documentations of their activities and child-created collections and artifacts. Various common spaces are created for children’s work and play, such as a block area, a dramatic play area, and an art/atelier area, among others.

High-quality classrooms for young children today are a reflection of the basic principles common to each of these approaches. The physical environments of challenging, supportive climates are intentionally planned and prepared with children’s total development in mind and are, in part, created with children. Activity areas allow for children to work together for blocks of time, so that social competence is naturally promoted. Materials, displays, and furniture arrangement are modified as needed, based on teachers’ thoughtful observations of children’s needs. Children’s interests and activities determine the ongoing creation of a dynamic, learning environment, always responsive to the learners themselves.

Emotional Climate

Knowledgeable early childhood educators recognize the power of the emotional climate to influence children’s growth in learning and development. A positive emotional climate is one in which children *feel* valued, respected, and embraced as a member of a group; a negative emotional climate,

then, is such that children might *feel* devalued, disrespected, and outside of a group. Although no classroom is perfect in terms of the emotional climate, teachers of young children strive to create and maintain a positive emotional climate that best supports and challenges young learners.

Verbal Interactions

In high-quality early childhood classrooms, verbal patterns reveal that teachers listen attentively to children, indicated by moving to the child’s eye level and maintaining eye contact. Positive verbal responses from the teacher may acknowledge the child’s communication, may challenge the child to think further, and may extend the child’s use of language. For example, a 3-year old might state, “Water spilled,” to which a teacher might reply, “Yes, the water did spill out of your cup. What should we do about that?” In this case, the teacher has acknowledged the meaning of the comment, has extended the child’s language (through the use of a complete sentence), and has challenged the child to think about how to solve the problem. A less supportive response would be for the teacher to clean up the mess, simply saying, “It’s okay; I’ll take care of it.” Although such a comment may not explicitly communicate disrespect, it certainly doesn’t challenge the child as a capable, thinking learner.

With children in the primary grades, the same principles apply to supportive verbal interactions. Teachers respond to children in ways that acknowledge their thinking but also stretch them to think further. For example, when asked what the inside of a pumpkin is like, a first grader might respond, “I think it’s cheese,” to which a teacher could reply, “That’s an interesting idea. Why do you think there is cheese inside the pumpkin?” Clearly, the child’s thinking has been acknowledged, and further thinking has been suggested. Conversely, if the response is “Well, it couldn’t be cheese, since this is a pumpkin,” it has been communicated to the child (and to the other children) that one should answer a question only when absolutely certain that it is correct, from the teacher’s perspective. Repeated responses of this type can also send the message to

a child that he or she is not a capable learner, since his or her thinking is not valued by the teacher.

Guidance Strategies

Positive guidance promotes young children's understanding that they are capable of making choices that serve them well and that are respectful of others. Consistent use of positive guidance strategies facilitates children's development of self-regulation skills, also referred to as executive function. There are numerous methods indicative of positive guidance, including redirection of children's attention, the provision of choices in the classroom, use of natural and logical consequences for challenging or inappropriate behavior, and facilitation of children's problem-solving efforts when conflicts occur. Positive guidance is predicated on the knowledge that children are capable learners and that, with adult guidance, they can learn to respect others and themselves in a classroom community.

Within a high-quality environment for young children, rewards and punishments are avoided; dependence on adult control of children's behavior and academic performance can result from the use of rewards and punishments, rather than the desired outcome of growing self-regulation ability. A climate most conducive to young children's learning and development is based on respectful relationships between adults and children, as well as among the children; a learning community built on such relationships is a necessary component of a positive guidance approach.

Cognitive Conditions

For young children to be optimally supported in terms of their developing intellectual capacity, thought must be given to the conditions for learning. Once again, the knowledgeable teacher of young children acts with intention to maintain a climate that is consistent with young children's developmental characteristics, as well as their individual interests and abilities. Thus, the cognitive conditions for learning take into account the natural tendency of young children to wonder, to

explore, and to investigate. Children are understood to be naturally curious and can even be thought of as scientists, as they question and attempt to make sense of their worlds.

Responsive Curricula

Exemplary classrooms for young children utilize responsive curricula, with a strong emphasis on direct, first-hand experience. Topics of study are often generated with children and are based on their interests. Teachers may also pique children's interest in a topic, through introducing materials or experiences that the children will find relevant and interesting. Additionally, the use of responsive curricula implies that there is a predictable routine and rhythm to daily activity but that specific time allotments are flexible and that blocks of uninterrupted time are necessary for children's deep engagement to occur.

Challenging curriculum for children is often described as "emergent": Although curriculum is partially and tentatively preplanned, the specific processes and experiences involved in a study are changed and shaped with the children. In other words, as children engage with materials and investigate topics, teachers observe their interests, note their questions and observations, and respond through the provision of additional resources and planned experiences. Inquiry learning and the project approach are both examples of curricula that are emergent and that challenge children to think deeply and critically.

Choices

Child-initiated activity, or choice, is a hallmark of quality in early childhood programs. When children are afforded opportunities to select from among a variety of meaningful, purposeful learning activities, they are typically more committed to the work they have chosen. In addition, choice allows children to function at present levels of development, thus strengthening skills they have acquired. For example, a child may select a puzzle that has been successfully completed in the past, or a book that has already been read, in order to gain

proficiency and confidence through practice of known skills. On the other hand, choice provides ample opportunity for children to challenge themselves appropriately, in the absence of imposed pressure. In other words, when a child chooses to create a complex block structure, or to record the exact number of wheel rotations in the gerbil cage, without being required to do so, the child is free from outside expectations. Thus, the mental energy required to think and persevere in challenging situations is available to the child rather than compromised by the threat of imposed expectations.

Intellectual Risk-Taking

Environments that support cognitive growth are established with a view of errors as valuable and important to continued learning. Teachers of young children accept children's mistakes in thinking as signs that they are, indeed, mentally capable; teachers also attempt to understand children's ways of thinking, when errors occur, and often find that from the child's perspective, there is logic in the error. Exemplary teachers guide children to see mistakes as opportunities to keep growing and learning, thus supporting children's dispositions toward life-long learning. Freedom from the fear of making mistakes allows children to progress in all developmental domains and curriculum areas, as they are more likely to feel respected, to be confident, and to think beyond imposed expectations for performance. Thus, environments that support intellectual risk-taking increase the likelihood that children will think deeply, critically, and creatively.

Whether in care settings prior to formal schooling or in the early years of formal education, young children's development and learning are ideally supported through intentionally created climates. High-quality environments for children are designed to challenge growth in all domains, while also nurturing children as the unique individuals they are. Young children are well-served in challenging, supportive climates, thoughtfully prepared and maintained by knowledgeable early childhood professionals.

CHALLENGING BEHAVIOR

Challenging behavior refers to behavior that interrupts and/or interferes with learning and/or optimal interactions with others. Research has shown that when children engage in challenging behavior in early childhood, these behaviors often persist throughout schooling and into adulthood. This entry provides information regarding perceptions of challenging behavior, common characteristics of challenging behavior, the impact of challenging behavior, and interventions that can be used to prevent and address challenging behavior.

Perceptions of Challenging Behavior

In many ways, challenging behavior is largely determined by the perception of the observer. As

is true with all aspects of human behavior, challenging behavior is individualized and, therefore, is contextualized based on one's personal, professional, and educational experiences. For example, if a person was raised in a home with very strict rules and expectations, that person may expect the same from children. Likewise, the way that individuals parented may also impact the way that those individuals interact with other children and perceive children's behavior.

Some early childhood professionals are able to draw distinct boundaries between their professional and personal perceptions of behavior, and at times these perceptions may be contradictory. For instance, an early childhood teacher may be very calm and patient with the young children in his or her classroom; however, at home, the teacher may be much less patient and understanding of his or her own children when they exhibit challenging behavior. In addition, the education and/or training that teachers have received can also influence perceptions of behavior. If a teacher did his or her student teaching with a cooperating teacher who was very harsh and often put children down, that student teacher may have a tendency to mirror this behavior in his or her future practice, even though he or she may know it is not appropriate. Of course responses to behavior on any given day may also vary based on a person's mood and/or cognitive state. For example, an individual who was up all night with a sick child at home and then gets a flat tire on the way to work may be much less patient than usual in interactions with children and responses to challenging behavior.

These examples demonstrate that defining, preventing, and addressing challenging behavior is not an exact science. With that being said, individuals' perceptions shape who they are and their interactions with young children. This is certainly true of interactions and responses to young children who are engaging in challenging behavior.

After a child has exhibited a challenging behavior numerous times, many individuals bypass all logical thoughts about understanding and/or addressing the behavior in developmentally appropriate ways and move straight to an emotional

reaction to the behavior. One of most difficult pieces of addressing children's challenging behavior is remembering that the role of the adult is to better understand the child's behavior and to find strategies to use in support of the child learning new skills to replace the challenging behavior. In other words, the child is not doing the behavior to us. In fact, his or her challenging behavior is probably not about us at all. Rather, the behavior is likely about a child who has a need that has not been met in other ways, and, for whatever reason, the child has found that exhibiting challenging behavior meets that need. Knowing this can sometimes help with refocusing responses on how to better understand and support the child.

Characteristics of Challenging Behavior

Despite the fact that everyone responds to behavior differently based on perceptions and experiences, there are some characteristics that are generally associated with challenging behavior. Considering the frequency, intensity, and duration of behavior can often help in determining whether or not a behavior goes beyond developmentally appropriate expressions. For instance, if 4-year old Joseph gets frustrated because Jordan took a toy from him and he pushes Jordan away to get the toy back, this is a developmentally appropriate response. That is not to say that we want to see this happening, but chances are, with some intervention, both Joseph and Jordan will learn how to share and take turns and how to respond appropriately when frustrated. If, on the other hand, Joseph's typical response in this situation is to scream, throw the toy at Jordan, and kick him, this would be more of a problem. Documenting the frequency, intensity, and duration of challenging behavior will usually reveal patterns in behavior that can help in determining why the behavior is occurring and how to prevent and address the challenging behavior in the future.

Examples of challenging behaviors that are sometimes seen in early childhood settings include but are not limited to (a) *verbal aggression*, including screaming, inappropriate language, and threats;

(b) *physical aggression*, including hitting, kicking, pinching, throwing objects, spitting, pushing, biting, and forcefully taking items from others; (c) *tantrums*, including prolonged crying, stomping, kicking, hitting, pushing, and head banging; (d) *destroying property*, including damaging other children's work, toys, or materials, or damaging classroom items; (e) *noncompliance*, including physical or verbal refusal to participate and/or follow directions; (f) *running*, including leaving the classroom or school property resulting in a safety risk to the child or others; (g) *inappropriate touching*, including the removal of clothing, and/or intentional urination or defecation; (h) *self-injury*, including hitting, kicking, biting, head banging, and cutting oneself; and (i) *withdrawal*, including retreating from all activities and alienating oneself from others.

Impacts of Challenging Behavior

Over the past 20 years, early childhood teachers and administrators have reported a significant increase in the number of young children who are beginning their school experiences without the emotional, social, behavioral, and academic skills necessary for school success. These children tend to have high levels of intense challenging behavior that are not responsive to developmentally appropriate behavior management strategies and practices. In fact, evidence suggests that about 25% of kindergartners arrive at school with significant challenging behavior.

Unfortunately, challenging behavior displayed in early childhood settings is often dismissed as age or developmentally appropriate forms of communication. Experts in the field have shown the importance of addressing challenging behaviors at an early age and that there are consequences if these behaviors are not addressed early in life. For instance, in many cases, when challenging behavior is not addressed during the early childhood years, these behaviors are likely to become more intense and less responsive to intervention efforts. In fact, research has demonstrated that challenging behavior identified during the preschool years that is not addressed often persists over time, resulting

in adolescents who may be identified as having emotional disturbances.

For children who continue on a developmental pathway to a diagnosis of emotional and behavioral disorder, the outcomes are grim. Evidence shows that students who are identified as having emotional and behavioral disorders have about a 50% chance of dropping out of school. Moreover, post-school outcomes for these individuals are also disheartening, including low employment levels, poor work histories, and low wages. During elementary and middle school, these students are at a greater risk for a number of social problems, including school bullying, gang-related activity, substance abuse, juvenile offenses, and acts of violence. These outcomes have been found to act as accelerators and predictors for adult violence and criminal behavior. A direct connection exists between challenging behavior in preschool and antisocial behavior in adolescence and adulthood when early expressions of problem behavior are ignored.

Along with concerns regarding the enduring nature of young children's challenging behavior, evidence also suggests an increased understanding of the interrelatedness among social and emotional development, cognitive development, the acquisition of pre-academic skills, and preparedness for school. Self-confidence, relationship skills, self-management, and self-regulation are among the social and emotional competencies necessary for successful participation in group learning situations. Preschool children with deficits in these critical skill areas are more likely to become children with challenging behavior.

Interventions

Research confirms that greater numbers of children are entering preschool and kindergarten with more complex and challenging behavior than ever before. As a result, there is an increased interest in providing systematic and comprehensive interventions to children during the preschool years. The primary settings in which these efforts are likely to occur are early childhood programs such as public or private preschool centers, child care programs, and/or

Head Start. Regrettably, many early childhood programs are not adequately prepared to meet the complicated needs of children with emotional delays and/or challenging behavior. Consequently, many children with more involved and intensive needs are removed or are at risk for being removed from developmentally appropriate settings as a direct result of their challenging behavior.

Because children with more problematic behavior have intensive and ongoing needs, simply placing these children in preschool programs, child care centers, Head Start, or other early childhood environments is not enough. In the past, many teachers have applied “one size fits all” reactive strategies and rules to complex problem behaviors, which in turn tend to cause challenging behavior to accelerate and intensify rather than decrease and diminish. Children with intensive behavioral needs require more individualized, systematic, and multifaceted behavioral approaches that go beyond typical intervention strategies to understand and change their behavior.

Several theories have been proposed for understanding, preventing, and addressing challenging behavior. Humanistic approaches, associated with theorists such as Carl Rogers, Rudolf Dreikurs, and Abraham Maslow, focus more on the underlying causes of behavior, recognizing individual differences and seeing children’s social and emotional well-being as the center of all learning. A humanistic classroom has shared responsibility, embodies mutual respect, and values and promotes self-regulation of behavior. From this perspective, teachers and others who know the child well seek to understand a child’s “mistaken goals” of behavior. Humanists believe that not all behavior is observable and that the role of the adult is to seek understanding and support the child with challenging behavior to develop a stronger sense of self-regulation.

Diverging from the humanistic view, behaviorism is a learning theory that is built on the theories of Ivan Pavlov (classical conditioning) and Albert Bandura (social learning), and is most closely associated with the works of B. F. Skinner. Foundational beliefs of behaviorism are that all behavior is functional and that all behavior can be

observed, measured, trained, and changed through reinforcements and punishments. A behavioristic classroom tends to focus on the use of rewards and punishments to regulate student behavior. According to behaviorism, only observable behaviors should be examined because internal states (i.e., cognitions, emotions, moods, and choice) are too subjective. Hence, from a behaviorist perspective, teachers and others would carefully observe a child with challenging behavior to look for patterns in behavior that would help them to understand why the behaviors are occurring and then design interventions to extinguish undesired behavior and reward desired behaviors.

Although both humanistic and behavioristic theories have merit in helping us better understand human behavior, in early childhood settings, a combination of these two perspectives is often used when seeking to understand and address children’s challenging behavior. One framework, the pyramid model, has been successful in merging these two views to help children develop self-regulation skills (humanistic) and understand behaviors through observation and functional behavior assessment (behavioristic). The pyramid model is a multitiered framework, which focuses on the establishment of universal strategies, including building positive relationships with children, families, and coworkers and creating high-quality supportive environments in efforts to promote social and emotional competence and to prevent and address challenging behavior. Preventative practices, such as developing and maintaining predictable schedules, minimizing the number of transitions, and providing visual reminders help all children better understand their environment, hence reducing some challenging behavior. The pyramid model also promotes the intentional planning and teaching of social and emotional skills to young children who may be lacking abilities in areas such as language, social, or emotional development. By teaching children to solve problems, resolve conflicts, manage their anger, and use friendship skills, children learn to use these skills in place of challenging behavior.

Unfortunately, in some cases, even when developmentally appropriate strategies such as those described in the previous paragraph are in place to prevent and address behavior concerns, children continue to engage in challenging behavior. For these children who exhibit the most intensive and persistent challenging behavior, individualized interventions are warranted. When addressing the needs of these children, a functional behavior assessment should be conducted to determine the function, or why the behavior is occurring. Functional behavior assessments are conducted through observations of the child in multiple settings, document analysis, and interviews with those who know the child best to learn more about what triggers and maintains a problem behavior. A team of individuals, including the child's teacher, family members, administrators, behavior specialists, and others, meet to review this information and use it to develop a comprehensive plan called a behavior support plan to prevent and address the challenging behavior.

The behavior support plan includes prevention strategies, replacement skills, and new responses by the adults to both the problem behavior and to the appropriate behaviors or replacement skills that are being taught. This level of intervention requires that staff and administrators collaborate with families and community partners to access and coordinate needed resources and supports to ensure that the behavior support plan is implemented with fidelity. Parents and guardians should be involved throughout the development and implementation of this plan and should learn effective behavior management skills to use at home and in other settings. The effectiveness of this intervention depends on consistent implementation across all of the child's natural environments (e.g., home, school, child care). After the plan is implemented, data are gathered to confirm that the interventions being used are working and that the child's challenging behavior is being replaced with more appropriate behavior.

CHECKLISTS AND RATING SCALES

Checklists and rating scales are formal and informal assessment methods frequently used to obtain information from a variety of sources about young children's development and learning and their environments in order to make important decisions about teaching and program improvement. Checklists provide a method for assessing presence or absence of a skill, behavior, or knowledge in a child and are typically formulated as "yes" or "no" questions. Rating scales are similar to checklists except they assess the *degree* of accomplishment of skill, behavior, or knowledge instead of just the presence or absence of it. Rating scales typically list performance statements in one column and the range of accomplishment in descriptive words, with or without numbers, in other columns (e.g., *never, always, sometimes*). This entry discusses the purpose of checklists and rating scales used to assess young children's development and learning and their environments, cautions about the use of these instruments with culturally and linguistically diverse students, and gives examples of checklists and rating scales that are used with young children.

Valid and reliable checklists or rating scales can quickly provide useful information about children's skills, knowledge, behaviors, preferences, and interests. They can be used for a variety of purposes such as developing children's goals, planning for intervention, and monitoring progress. They are frequently used to screen young children for a presence or absence of disabilities and ensure that they are recommended for further in-depth evaluation if they fail the screening. Furthermore, the information from rating scales and checklists can be utilized to improve the program and its teaching strategies. Checklists and rating scales may be completed by family members, caregivers, practitioners, or administrators who are involved in gathering the information.

Use of Checklists and Rating Scales With Diverse Population

Given the changing demographics of the population of young children, and the inherent complexities

and variability of bilingual language development, Linda M. Espinosa and Michael L. López remind us of the urgent need for the development of clear definitions, recommendations, and resource materials to guide the different types of assessment approaches that are accurate and valid for this unique and rapidly growing population of linguistically and culturally diverse English language learners. Researchers recommend involving families when conducting assessment using checklists or rating scales that are nondiscriminatory and take into account the importance of individual background and history while respecting the child's primary language and home culture. Further, experts caution against the overreliance on standardized, norm-referenced tests during the early childhood years, particularly for the assessment of children from linguistically and culturally diverse backgrounds.

Examples of Checklists and Rating Scales to Assess Young Children and Their Environments

Checklists and rating scales that can be used to assess young children and early childhood classroom environments include the following.

Behavior Assessment System for Children, Second Edition (BASC-2) is a comprehensive standardized tool used to assess adaptive and maladaptive behaviors and self-perception of children and youth from 2.5 to 25 years of age. Parent and teacher rating scales allow complete and multidimensional information.

Behavioral and Emotional Screening System (BESS) is designed to help school personnel and other care providers determine the behavioral and emotional strengths and needs of students and concerns regarding students between the ages of 3 and 18. There are parent, teacher, and student forms available, with each ranging from 25 to 30 items.

Childhood Autism Rating Scale (CARS) is used for the detection and diagnosis of autism. The CARS consists of 14 domains assessing behaviors associated with autism, with a 15th domain rating general impressions of autism. Each domain is scored

on a scale ranging from 1 to 4; higher scores are associated with a higher level of impairment.

The Child Behavior Checklist (CBCL) is used to assess children for various behavioral and emotional problems. The preschool forms and profiles span ages 1.5 to 5 years. The parents, child care providers, and teachers provide ratings on 99 problem items and descriptions of the child's strengths and problems.

Connors Early Childhood is a multidimensional psychological instrument used to assess behavior for children ages 2 to 6. The instrument aids in the early identification of behavioral, social, and emotional problems such as inattention, hyperactivity, anxiety, social functioning, and moods.

Early Childhood Environment Rating Scale-Revised (ECERS-R) is an environment rating scale used to assess the quality of group programs for children ages 2 through 5. The total scale consists of 43 items organized into seven subscales. Each item is rated on a 7-point scale.

Infant/Toddler Environment Rating Scale-Revised (ITERS-R) is an environment rating scale designed to assess the quality of group programs for children from birth to 2.5 years of age. The total scale consists of 39 items organized into seven subscales. Each item is rated on a 7-point scale.

MacArthur-Bates Communicative Development Inventory (CDI) is a standardized tool used to assess early language skills for children ages 8 to 37 months. CDI is completed by caregivers to help professionals screen young children's emerging language and communication skills. It includes three areas: CDI: Words and Gestures (for use with children 8 to 18 months); CDI: Words and Sentences (for use with children 16 to 30 months); and CDI-III (for use with children 30 to 37 months).

Modified Checklist for Autism in Toddlers-Revised (M-CHAT-R) is a scientifically validated 2-stage parent-report screening tool to assess risk for autism spectrum disorder. The 20-item checklist is

used with children between 16 and 30 months of age. Children who fail the screening should receive a more thorough assessment for possible early signs of autism spectrum disorder or developmental delay.

Preschool and Kindergarten Behavior Scales, Second Edition (PKBS-2) is a standardized behavior rating scale designed for use with children ages 3 through 6 years. It includes 76 items on two separate scales to provide an integrated and functional appraisal of the social skills and problem behaviors of young children from parents, teachers, and other caregivers.

CHILD ABUSE PREVENTION

According to the U.S. Department of Health and Human Services, child protective services agencies received approximately 3.4 million referrals for child maltreatment in 2010; 78.5% included neglect, 17.6% physical abuse, and 9.1% sexual abuse. In addition to physical injuries, physical disabilities, and abuse-related fatalities, child abuse is associated with acute and long-term psychological, physical, and neurological difficulties; related chronic health problems; mental health care needs; and expenses associated with child welfare, law enforcement, special education, and the judicial system. Richard J. Gelles and Staci Perlman have estimated that child abuse costs \$80 billion a year in both direct costs, such as medical treatment for trauma and child welfare expenses, and indirect costs, such as the increased need for early intervention and special education services. Child maltreatment is a critical public health issue with significant justification for prevention programming.

Child maltreatment prevention has historically utilized a health care model, including primary, secondary, and tertiary prevention. Primary prevention is the most universal and targets factors in the general population that contribute to child maltreatment (e.g., community violence, corporal punishment acceptance, poverty), aiming to avoid initial maltreatment occurrence. Secondary, or selective, prevention targets specific, high-risk groups with significant child maltreatment risk factors (e.g., poor parent-child interactions, parental mental health concerns), attempting to detect ongoing maltreatment and prevent it from continuing. Tertiary, or indicated, prevention focuses on populations where child maltreatment has already occurred (e.g., child welfare) to prevent future occurrence. The majority of research has focused on secondary and tertiary prevention, although work has begun focusing on primary prevention methods.

Child Sexual Abuse

As an initial step in reducing child sexual abuse (CSA) and its subsequent negative outcomes,

experts have recommended educating the general population about CSA and risk factors. Community-level media campaigns such as print, radio, and television public service announcements and informational brochures show potential for knowledge and behavior change. Initial case study findings from a statewide education and community mobilization effort, the Enough Abuse Campaign, are promising. Most CSA prevention efforts have included enhancing knowledge, competencies, resources, or coping skills in children, caregivers, and child care professionals.

Child-Focused Programs

The most common strategies have educated children about CSA using school-based programs that teach children to recognize inappropriate adult behavior, resist inducements, react quickly to leave the situation, and tell someone about the incident. Concepts include body ownership, the touch continuum ("okay" vs. "not okay" touches), acting on intuition, secrets, saying "no," and locating helpful people to tell. Research suggests significant improvements in abuse-related knowledge following child participation in a CSA awareness program, with greater increases in CSA knowledge and prevention skills when the child's parent plays a role in the teaching. However, in a 2003 review of prevention strategies, Rebecca Bolen noted that it is doubtful that simply targeting potential child victims will decrease CSA, as adequately preparing children for diverse approaches of potential offenders may prove difficult.

Caregiver-Focused Programs

Caregivers are in a unique position to decrease CSA risk. Through daily contact with children, they have ample opportunity to provide repeated exposure to CSA information and self-protection skills. Furthermore, as indicated in the National Survey of Adolescents, a large-scale epidemiological survey, the majority of CSA is perpetrated by a family member or nonrelative the child knows; thus, increasing the need for parental knowledge and monitoring (e.g., checking children's Internet use,

preventing unsupervised time with other caregiving adults such as babysitters and coaches, supervising older children who are playing with younger children) may impact children's abuse vulnerability.

Research indicates that parents' knowledge about CSA and prevention are often inadequate. In a community based survey of caregivers, Leslie Tutty found that only roughly half of caregivers report having discussed CSA with their preschool-age children. Furthermore, child abuse researcher Esther Deblinger has found that parents who talk to children about CSA often focus on strangers as potential offenders and provide little specific information about the nature of CSA. Despite books and videos to help parents address this topic, such as the 2003 book *Let's Talk About Taking Care of You: An Educational Book About Body Safety*, by Lori Stauffer and Deblinger, effectiveness research is limited. Workshop-based parent-focused CSA preventive programs increase parental knowledge and increase the likelihood that caregivers will discuss CSA with their children; limited information is available as to whether these programs prevent CSA.

Child Care Professional-Focused Programs

A more wide-reaching prevention strategy focused not only on parents but also on any adult who has contact with children (e.g., teachers, pediatricians, clergy, coaches, child care providers) may prove fruitful. Because of their accessibility to children and expertise in child development, these professionals can promote secondary prevention by identifying possible CSA cases and intervening. At an organizational level, professionals can utilize effective screening techniques for new employees and volunteers, specific guidelines regarding one-adult/one-child situations, and reporting policies to reduce CSA incidence.

Interventions targeting child care professionals such as the CSA Prevention: Teacher Training Workshop Curriculum and Darkness to Light's Stewards of Children have effectively impacted knowledge, attitudes, and potential protective behaviors and show high acceptance and feasibility across diverse ethnic groups. Alyssa Rheingold

and colleagues found minimal differences between the in-person and Web-based delivery modes of the Stewards prevention training programs, suggesting that these modes of training were equally effective. Like child and caregiver programs, child care professional programs impact knowledge and behavior, but it is unclear whether they decrease CSA incidents and prevalence.

Child Physical Abuse and Neglect

Although neglect accounts for a large majority of child maltreatment reports, most existing prevention programs dually target child physical abuse (CPA) and neglect. Because of high CPA and neglect prevalence early in development, and increased risk for negative outcomes during this time, early childhood is a critical period for prevention. Based on research, many programs target proxy measures of CPA and neglect such as parent-child interactions, child well-being, parent stress, and child disruptive behavior. Early prevention programs have demonstrated effectiveness for decreasing CPA and neglect in families of young children from a range of sociodemographic backgrounds.

Caregiver-Focused Programs

Although there are multiple causes and explanations for CPA and neglect, the U.S. Department of Health and Human Services reported in 2012 that caregivers are the most frequent perpetrators, and research has found abuse is often associated with limited knowledge of effective parenting practices. Behaviorally focused parent management training (PMT) programs increase positive parenting practices and child coping, and decrease child disruptive behaviors, as well as emphasize CPA and neglect directly.

The majority of established CPA and neglect prevention programs include one-on-one interventions with trained providers (e.g., Project SafeCare, nurse home visiting programs, Healthy Families America, parent-child interaction training). Although programs differ in focus and content, topics often include parent education and support around effective parenting practices targeting risk for abuse.

Although individualized PMT programs are effective in preventing CPA and neglect, implementation barriers present challenges in delivery to high-risk families, especially when they have not been referred and may not seek services on their own. Barriers can range from personal conflicts (e.g., work schedules, finances, time) that preclude parent engagement, to implementation barriers (i.e., intense therapist training, high costs) that challenge dissemination outside of substantially funded research programs. Home-based interventions address these barriers and are found to be particularly effective. For example, Project SafeCare targets prominent CPA and neglect risk factors; includes core modules on child health, home safety, and parent-child/parent-infant interaction; and has strong evidence for CPA reduction and recidivism across settings.

Caregiver-Focused Programs in Community-Based Settings

Group PMT provides a practical option for parents in community settings that are not specifically referred. Individual PMT is most effective at promoting positive child and parent outcomes, but evidence for the efficacy and cost-effectiveness of group PMT also exists. Individual PMT aims to produce large effect sizes for specific parents, while group programs focus on reaching as many people as possible with an efficacious treatment, increasing overall public health impact of this type of prevention.

Several group PMT programs address CPA risk factors in young children (e.g., Group Triple P, 1-2-3 Magic, Parenting Wisely, The Incredible Years) and typically range from 2 weeks to several years. Whereas these programs focus on similar PMT skills (i.e., effective discipline strategies, establishing routines), their presentation differs considerably. In Group Triple P, the parenting program serves as one component of multiple systems, from the broader community to classroom teachers, and families often remain involved for up to 10 years. On the other hand, 1-2-3 Magic and Parenting Wisely are stand-alone programs that use commercial video/CD-ROM and can be completed in less

than 6 hours. The Incredible Years is a 22-week, community-based program implemented within existing structures where children receive a range of services, including PMT, home visiting, parent-child relationship enhancement, social skills training, and academic tutoring.

Professionals-Focused Programs

Targeting primary and secondary prevention, recent programs have focused on primary care and other pediatric settings. Pediatric settings have expanded their routine review of systems to include abuse screening, and professionals are trained to use clinical judgment in assessing for potential abuse. For example, the Safe Environment for Every Kid (SEEK) model was initiated in pediatric primary care to focus on training professionals and paraprofessionals to identify child maltreatment risk, screen for abuse, and provide case management for identified cases. Studies have demonstrated promising results.

Discussion

Child maltreatment is a significant public health problem that warrants a multimodal prevention approach. Differing approaches and target populations are needed to address various forms of maltreatment. Across all types of child maltreatment, however, there is clear importance to target prevention not only on an individual level but also a community level. Further interdisciplinary detection and prevention efforts are crucial. Yet, despite the obvious advantages and wide appeal of child maltreatment prevention, existing research has significant limitations. For example, one of the biggest limitations within the CSA field is the lack of controlled trials that directly assess the impact of prevention programs on CSA incidents. Although citizens might view child abuse prevention as an important goal, this has not translated into policy support for methodologically rigorous program evaluations or widespread dissemination efforts.

CHILD CARE

Child care refers to care for children provided by a person other than a parent or legal guardian. Child care is typically seen as distinct from classroom education at the kindergarten level and higher. It can be offered in formal settings, such as child care centers or Head Start programs; by people with a range of training and/or experience, such as those with degrees in early childhood education; or by relatives or friends. Some professionals in the field prefer the term *early care and education* to the term *child care*, because of an interest in emphasizing the importance of quality early learning to children's development, and to convey the degree of professionalism required to maintain a strong public system of care and education. Despite that, many continue to use the term *child care* to refer to both formal and informal arrangements.

In the majority of families in the United States, all parents in the household participate in the paid

labor force, making child care an essential element of parents' ability to work and to maintain economic security for their families. Because mothers still tend to take on more parental care for children than fathers, child care is especially important for women's ability to participate in the paid labor force. Strong early care and education systems are a critical component of community economic development and a strong national economy.

Quality care and education experiences also contribute positively to children's cognitive and social development and school readiness, especially for children among low-income families. Research finds that quality early care and education is associated with improved adult outcomes decades later, including higher educational attainment and improved economic outcomes. This entry discusses types of child care and families' utilization of different sources of child care; the cost of child care and sources of assistance; and child care quality, licensing and accreditation, and quality improvement initiatives.

Types and Use of Child Care

Types of Child Care

Families utilize an array of types of child care. Relatives and nonrelatives—such as a babysitter, neighbor, or friend—often provide care to children, in either the child's home or the home of a relative or nonrelative. This form of child care is sometimes referred to as *family, friend, and neighbor* (FFN) care.

Family child care is care provided by a nonrelative in his or her home to multiple children of different families. The care is provided as part of an ongoing business, unlike FFN care provided by a nonrelative. Licensing requirements for family child care homes vary by state.

Center-based care refers to organized child care in a nonhome setting, such as a day care center, nursery school, preschool, Head Start program, or after-school program. Child care centers generally group children by age. Center-based care facilities are required to meet licensing standards that vary by state. These standards include limits on the number of children per care provider that differ

according to age, health, and safety standards, and a required number of provider training hours.

Preschool programs typically serve 3- to 5-year-old children who are not yet in kindergarten. The federally funded Head Start program, for example, serves low-income preschool-age children. In addition, a number of states provide public funding for preschool programs. Children attend preschool programs on a school-day schedule that can range from several hours per day to full days.

Utilization of Child Care Arrangements

Research by the U.S. Census Bureau finds that 61% of children younger than 5 years are in a reoccurring and regular care arrangement at least once per week. Of these children, about four in ten receive care from a relative, three in ten are cared for by a nonrelative (including child care centers or in a provider's home), and about one in ten are cared for regularly by both. Among families living below poverty, relative care is much more common: 85% of children younger than 5 years who are below the poverty level receive relative care as their primary care arrangement. A family's choice of child care arrangement can be affected by a variety of factors, including cost, the family's socioeconomic status and household composition, age of children, children's health needs, employment circumstances and schedules, available information on child care options, and preferences related to cultural backgrounds of providers.

Child Care Costs and Financial Assistance

Cost of Child Care

For many parents in the United States the cost of child care represents a significant portion of their monthly expenses. In 38 states and the District of Columbia, two-parent families pay, on average, more than 10% of the state median income for center-based infant care. Child care represents an even greater share of single parents' budgets: In every state, single parents pay more than 20% of median income for center-based infant care.

Child care is often more costly than other common family expenses, such as rent, food, or even college tuition. Child Care Aware of America finds that care for an infant at a child care center is more than twice the amount a family spends on food in all regions of the United States. Costs for a 4-year-old in a child care center are higher than public 4-year college tuition and fees in 20 states. Child care costs are particularly burdensome for low-income families. The U.S. Census Bureau found that in 2010, families who earned less than \$1,500 per month spent, on average, 49.5% of family income on child care.

Financial Assistance for Child Care

The federal Child Care and Development Fund provides resources to states to help low-income families access quality, affordable child care while parents work or attend education or training activities. States provide subsidies to families that meet income and other eligibility requirements. Child care subsidies, however, are limited and often difficult for many families to obtain. In 2011, only 17% of the 14.3 million federally eligible children, defined as all children of families with incomes below 85% of state median income, received subsidies.

States often put their own, more stringent eligibility criteria in place, such as income caps and limitations on eligibility when parents are searching for a job. According to the Department of Health and Human Services, in 2011, just 29% of the 8.4 million children eligible under state eligibility rules received assistance. As of 2014, 18 states had waiting lists or had frozen intake for families applying for child care assistance.

The United States, on the whole, provides fewer public child care supports to families as compared with other high-income countries. Policy makers and advocates are working to expand the support of affordable, high-quality child care options in the United States, but the need for such options significantly exceeds the supply. In the United States the primary sources of child care funding are the Child Care and Development Block Grant, the Head Start program, and state child care and pre-K budgets.

Total federal and state spending would need to increase substantially to ensure widespread access to quality, affordable care.

Quality of Child Care

Elements of Quality

The Cost, Quality, and Outcomes Study of early child care, a large, longitudinal study of child care in the United States, found that child care quality characteristics were related to positive social and cognitive outcomes for children, with structural factors and process quality making a difference in child outcomes. Structural quality refers to characteristics of child care, such as group size, staff-to-child ratio, facility size, and the training, qualification, and compensation of care providers. Process quality refers to factors such as the positivity, intimacy, and social elements of the relationship between the caregiver and child, as well as the provider's teaching style. For example, high process quality is characterized by caregivers interacting often and in close contact with children, encouraging expression of feelings and ideas, listening attentively, and smiling. Structural quality components are thought to facilitate an environment with high process quality. For example, an environment with a low staff-to-child ratio (one element of high structural quality) enables the potential for a caregiver to be engaged with each child (an element of high process quality).

Licensing and Accreditation

Licensing standards are minimum requirements that must be met by a child care center or family child care home in order to operate. The standards include parameters for staff training and qualifications, child-to-staff ratios, and health and safety measures, among others. Specific requirements are set by each state, with licensing standards varying widely across the country. For example, for toddler care, maximum ratios range nationally from a low of 4:1 to a high of 12:1, with 8:1 being the most common ratio. According to National Center for Child Care Quality Improvement, in 2011 more

than 300,000 licensed facilities were operating with a capacity to serve 10 million children.

Several organizations provide accreditation opportunities to child care centers and homes, which require adherence to higher standards than those required for licensure. For example, the National Association for the Education of Young Children (NAEYC) developed national standards for programs serving children from birth through age eight. According to recent estimates, 6,500 currently accredited programs serve almost one million children.

Quality Improvement Initiatives

A number of quality improvement initiatives are under way across the United States. For example, 39 states have developed quality rating and improvement systems (QRISs), designed to incentivize and help programs improve quality, while providing information on quality to help families select programs. Facilities meeting QRIS standards typically receive training, mentoring, and technical assistance; receive financial incentives; and are subject to monitoring such as onsite visits, self-assessments, and document verifications.

One factor affecting the quality of child care is typically low wages earned by child care providers, relative to comparably skilled workers in other fields, which can negatively affect job retention and longevity in the field. According to the Bureau of Labor Statistics, in 2012, the median wage for a child care worker was \$9.38 per hour. Some quality efforts, including many QRISs, include wage ladders that offer child care providers higher wages when they attain additional training or credentials.

The federal Child Care and Development Block Grant (CCDBG) was reauthorized in 2014 for the first time since 1996, with new health, safety, and licensing requirements for facilities receiving funds. For example, states must standardize trainings on first aid, CPR, and prevention against sudden infant death syndrome, and providers must receive health and safety training before operating. States are also now required to inspect CCDBG facilities before

they receive licensure, and states must also inspect licensed CCDBG facilities at least once per year.

CHILD CARE ASSISTANCE AND CHILD DEVELOPMENT

Children are more likely to achieve long-term success when they begin school ready to succeed. But school readiness involves more than just a high-quality early learning experience. Children also are more likely to be ready for school when they have a stable, nurturing family environment with parents who have the economic security to promote learning. For many families, low-wage jobs with inflexible schedules and a lack of resources for high-quality child care create profound stress that inhibits the healthy environment children need for a strong start. Child care assistance for low-income families comes mainly from the federal Child Care and Development Block Grant. State and local governments contribute to a lesser degree with only very modest funding from the private sector. This help for families pays for all or part of child care expenses while parents work, seek work, or attend school themselves, and can make it more likely that children will start school ready to learn.

Child care can help parents get and keep a job or further their education, enabling them to concentrate at work or school knowing that their

children are well cared for. A nurturing environment for children promotes their learning and development. By helping families pay for child care, child care subsidies allow parents to work and earn the income necessary for their family, which is also important for children's development. A 2011 study by Greg J. Duncan, Pamela A. Morris, and Chris Rodrigues found a relationship between an increase in family income and children's achievement, with their results suggesting that a \$1,000 increase in a low-income family's annual income increased young children's achievement by 5% to 6% of a standard deviation. When parents earn a steady income they can offer their children more stability, opportunities, and resources. Families can live in better neighborhoods with better schools, provide nutritious meals, and buy books and other toys that allow their children to learn and explore.

The cost of child care is burdensome for low-income families. In 2013, the average cost of full-time child care for one child in a child care center ranged from about \$4,500 to \$16,500 annually depending on the age of the child and the state, according to Child Care Aware. Yet, only one out of six children eligible for federal child care assistance receives it, according to a 2015 report from the U.S. Department of Health and Human Services.

Child care assistance makes a difference in helping people get and keep a job. Research shows that when parents receive child care assistance, they are more likely to work. A three-state study in 2004 examining child care subsidy participation among families receiving and leaving welfare found that, controlling for various background characteristics, using a child care subsidy decreased the probability of ending employment over the study period by 25% to 43%. A California mother who left welfare and obtained a steady job after receiving child care assistance to attend school told *The Huffington Post*, "The stable child care was the linchpin" (Goodman, 2012).

Several studies have shown that families on waiting lists for child care assistance find it difficult to work. A 2005 Minnesota survey found that nearly three-quarters of parents had made changes

in their job or education plans, including nearly half who had to reduce and/or change their work hours and almost one-fifth who had to cut their school hours or quit school altogether. In North Carolina, about one out of four families on the state's waiting list for child care help had lost or had to quit their job while waiting for assistance, according to a 1998 study.

Knowing their children are in a safe environment reduces stress for parents and impacts how they interact with their children. Research demonstrates that stress negatively affects parenting, which can negatively affect child well-being. A 1999 study by Philip Coltoff, Myrna Torres, and Natasha Lifton found that 77% of the families on the waiting list for subsidized child care in New York City believed their current child care arrangements were negatively affecting their children.

Families unable to receive help are often forced to use a patchwork of unstable arrangements, causing disruption for children and more stress for parents. *The Huffington Post* article mentioned earlier also followed another California mother on the waiting list who was worried about leaving her children with relatives but had no choice because she needed to keep her job. She said, "When I leave, I just feel like I'm taking chances. But I don't know what else to do. I have anxiety a lot" (Goodman, 2012).

The benefits of child care assistance for children and their parents are intertwined—children are more likely to succeed when their parents can provide greater financial security, and parents are more likely to have the peace of mind and focus they need to work when they are confident their children are in good care.

CHILD CARE POLICY AND PRACTICE

Child care refers to regular nonparental care provided to children from birth to age 13 years. The U.S. child care system is a patchwork of child care centers, formal regulated and informal unregulated family child care homes, and relative or nonrelative providers in a child's own home that serves imperfectly the often competing missions of parental labor force participation and child development. Funded largely by parental fees and only partially subsidized by state and federal programs, the contemporary U.S. system reflects a cultural perception of child-rearing as a private rather than a public good.

This entry begins with an overview of contemporary child care practice followed by a brief history of child care policy in the United States leading to the creation of the Child Care and Development Block Grant (CCDBG), or Child Care Development Fund as it is alternately called. It then examines price as a barrier to child care access and the role of the CCDBG in enhancing access, explores the intersection of policy and child care quality in the face of the CCDBG, and comments on evolving evidence of links between child care policy and the dual outcomes of parental employment and child development.

Contemporary Child Care

Contemporary child care is one component of the larger U.S. early childhood education and care system that also includes early education provided through federal Head Start and Early Head Start programs, private or state-run prekindergarten programs, and early childhood demonstration programs typically linked to research centers. A given child care program may include early childhood education components, or it may serve a primarily or exclusively nonparental supervisory function. However, as parents frequently access multiple forms of nonparental care in order to provide wrap-around coverage that meets their children's needs and their own work schedules,

child care and early childhood education are difficult to separate in practice.

The U.S. Census Bureau estimates that 8.2 million children (or slightly over 40% of all children under age 5) received one or more forms of regular nonparental care in 2011 for an average of 26 hours per week if their mother was working and 21 hours per week if their mother was not. The 2011–2013 edition of the *50 State Child Care Licensing Study* completed by the National Association for Regulatory Administration (NARA) indicates that care was provided by some 312,000 licensed facilities (including 107,000 licensed child care centers of which 71% were for profit) or by informal care providers.

The form of nonparental care accessed by parents differs by the age of the child, parental income, and other sociodemographics and by parental labor force status and work schedule. Specifically, compared to mothers who are employed part time, those employed full time are more likely to access center care or family day care and less likely to rely on relative care. Younger children of working mothers are less likely to be placed in center care than are older children. Children living below the poverty level and children of Hispanic origin are also less likely to be in center care than other children. Use of multiple care arrangements is common. According to the Census Bureau, 26.7% of children under age 5 with working mothers used multiple care arrangements.

History of Public Support for Child Care

Contemporary means-tested child care policy finds its roots in the notion of nonparental care of poor children as a charitable obligation of the social elite. In the late 18th through the early 20th century, free day nurseries run as charitable organizations with strong moral overtones and often with religious affiliation sought to support maternal employment as a last resort to family destitution and to reform what were perceived to be the bad habits of children raised in poverty. Working mothers unwilling or unable to submit to the stringent requirements and harsh judgments of

these day nurseries accessed a wide variety of informal care arrangements, including child self-care, pieced together out of necessity.

Although female labor force participation rates rose from less than 35% to more than 60% during the 20th century, cultural tension around the issue of voluntary maternal employment kept public child care policy at a standstill. Short-term federal funding to support nursery schools and child care centers during World War II, when women's employment was deemed a national need, represents a notable but temporary exception to the nation's lack of public child care support. Modest child care support for low-income families through mechanisms such as Title XX of the Social Services Block Grant (SSBG) and Title IV-A and IV-C of the Social Security Act of 1935 declined in real terms through the 1980s, even as efforts to move low-income unemployed mothers into the workforce intensified. Increased funding for Head Start—a means-tested federal school readiness program established in 1965 that includes a half-day early education component for 3- and 4-year-olds—provided some relief for the parents of preschool-age children, but the restricted hours of care rendered it of limited use to many working parents then and now.

Middle-income families fared somewhat better through expansion of the dependent care tax credit program during the 20th century. Begun as a tax deduction to subsidize employment-related child care expenses in 1954 and reformulated as a tax credit in 1979 for the same purpose, the program credits between 20% and 30% of annual child care expenses up to \$3,000 for one child and up to \$6,000 for two or more children, depending on family income level. At present, this program returns \$3.4 billion of benefits annually to dual-earner or single-parent working households. Because the credit is not refundable, it is of most value to middle-income earners. According to the Tax Policy Center, 85% of the total benefits in 2010 accrued to households earning between \$40,000 and \$200,000 annually.

The birth of contemporary public child care policy for low-income families through the creation of the CCDBG came finally as a by-product

of employment mandates included in welfare reform through the Family Support Act of 1988 and the Personal Responsibility and Work Opportunities Reconciliation Act (PRWORA) of 1996. Originally passed in 1990 and reauthorized in 1996 and 2014, the CCDBG integrates and expands funding previously provided under the Title IV Aid to Families with Dependent Children Child Care program, including transitional child care and at-risk child care programs, into a federal block grant administered by the states with discretion on program scope and eligibility.

CCDBG money flows to a state in three separate streams: Mandatory and discretionary spending allocations are determined based on the size of the eligible population while maintenance of effort (MOE) funding requires that states provide matching funding at the level that maintains effort prior to CCDBG implementation. Child care funding previously provided under Title XX remains a supplement to CCDBG, and states have the option to allocate a portion of their Temporary Assistance for Needy Families (TANF) block grant funding for child care provision as part of their MOE match.

Under CCDBG and its related programs, combined state and federal child care spending grew from under \$2 billion in 1991 to just over \$4 billion in 1998 to a high of nearly \$13 billion in 2011, although spending has since dropped to \$12 billion, according to Department of Health and Human Services data compiled by the Congressional Research Service and the Center for Law and Social Responsibility (CLASP). Roughly 1.5 million children are served by the CCDBG program annually, up from 1.3 million in 1997 but down from a high of 1.8 million in the mid-2000s. Fifty percent of the families receiving care under CCDBG had incomes below the poverty level and an additional 25% had incomes between 100% and 150% of the poverty level, according to 2010 estimates produced by the U.S. Government Accountability Office.

Despite the noted expansion in funding, according to Organisation for Economic Co-operation and Development (OECD) data the United States spends significantly less on preprimary education and care in real dollars per child and as a percentage of gross

domestic product than does the average OECD member nation, and the gap in spending is not closed by higher U.S. levels of private expenditure. Well-accepted evidence of the high social returns to early investment in children and families makes such low levels of spending potentially problematic.

CCDBG Policy and Access to Child Care

An explicit goal of CCDBG policy is to enhance low-income families' access to regular, formal child care that is constrained by high child care prices. The cost of full-time infant care exceeds 10% of the state median income for a married couple in 38 states and exceeds 25% of the median income of a single-parent family in all states, while the cost of full-time preschool care exceeds 10% of the state median income for a married couple in 19 states and exceeds 25% of the median income of a single-parent family in all but 6 states, according to a survey conducted by Child Care Aware. Considered another way, child care costs for a family with two children in care exceed the cost of housing and food in most regions of the United States and are comparable to a year's tuition and fees at a state university in many states.

Low-income working families who receive child care subsidies funded through the CCDBG and other smaller programs exhibit a higher likelihood of using formal licensed and especially center care. However, it is widely recognized that the subsidy programs currently in place are inadequate to meet the needs of the majority of low-income families. Only 17% of eligible families receive subsidized care through CCDBG and other sources. As of early 2013, growing waiting lists for child care assistance were recorded in 19 states, according to the National Women's Law Center. In addition to a lack of funding, studies cite structural aspects of the child care subsidy delivery system—such as lack of information on eligibility, application and recertification process burden, and perceived stigma—as additional factors in low subsidy take-up and note that take-up rates vary systematically by family characteristics. According to a 2012 Urban Institute report, state-level revision of

some CCDBG policy parameters has the potential to enhance child care access.

Where available, low-income parents of preschool-age children utilize state or school-sponsored prekindergarten programs or Head Start to provide part-time care in addition to that provided under CCDBG. According to 2012 data from the National Survey of Early Care and Education (NSECE), a comprehensive nationally representative compilation of data on child care supply and demand, 70% of school-sponsored programs and 81.4% of Head Start-funded programs provided free care to all parents. In the end, however, many parents unable to access formal regulated care to meet some or all of their schedule needs rely on family members or friends to provide low-priced or free informal care. According to 2012 data from the NSECE, roughly 72% of unlisted or informal home-based providers provided free care to children under 3 years of age versus only 9% of center-based programs and 5% of listed home-based providers.

Child Care Quality and the CCDBG

Analyses of the link between the quality of the child care setting and child developmental outcomes consistently identify modest but statistically significant positive correlations that are stronger in younger than older children and more pronounced in language and academic outcomes than social outcomes. Research further suggests the presence of a nonlinear effect in which a minimum threshold of quality is needed, with the highest quality care yielding far more substantial impacts on outcomes.

However, given the high price of quality care, parents are frequently forced into lower priced unlicensed and potentially lower quality care even when subsidies are present. According to the Department of Health and Human Services Administration for Children and Family, 19% of the children receiving CCDBG funding are in unlicensed care, with that percentage as high as 30% in some states. Although correlational studies on the link between subsidy receipt and care quality have yet to produce definitive results, low state

CCDBG reimbursement rates limit parental choice of providers and thus may decrease the quality of care received inadvertently. According to a 2012 summary of state child care policies conducted by the National Women's Law Center, only three states set the maximum child care reimbursement at the market rate of 75th percentile, with the remainder of the state reimbursements set at a lower level, often as low as the 50th percentile. Further, reimbursement is often complicated by paperwork requirements and evidence of ongoing parental eligibility, and subsidies require a parental co-pay averaging 10% of the price of care.

Quality enhancement provisions in the form of mandates and funding set-asides in the 1996 and 2014 reauthorizations of the CCDBG legislation suggest that access to child care of an adequate quality to support strong child outcomes is of concern to federal policy makers, but implementation of these quality enhancement provisions is complicated in practice. First, meaningful child care quality measurement is difficult. Historically, child care quality has been measured using both structural (e.g., child-teacher ratio, average class size, teacher education and training) and process (e.g., the nature of the child-teacher interactions, the structure of the learning environment) measures. But as of 2015, structural measures factored most prominently in child care licensing and regulation guidelines given the ease with which they may be quantified and despite their well-recognized inferiority as predictors of child development. The creation of a set of widely accepted quantifiable environmental rating scales including the Early Childhood Environment Rating Scale-Revised Edition (ECERS-R), the Infant/Toddler Environment Rating Scale-Revised Edition (ITERS-R) for center care, the Family Day Care Rating Scale (FDCRS) and the Family Child Care Environment Rating Scale-Revised Edition (FCCERS-R) for family day care settings, and, more recently, instructional quality measures such as the Classroom Assessment Scoring Scale (CLASS) allow for the possibility of more meaningful and accurate quality measures and guidelines moving forward.

Second, federal mandates rely on state implementation often without funding increases to support quality improvements. Recognizing the important role of quality in both parental choice and ongoing center assessment, states began constructing quality indices referred to as quality rating and improvement systems (QRISs) that draw on classroom assessment scales and environmental rating systems to effectively measure process quality. As of February 2015, all but seven states had QRISs in place and six were in the pilot or planning stages of QRIS. In a growing number of states, QRIS ratings are tied to financial incentives and rewards for the providers that partially offset their cost of quality increases, and state QRIS management is one of a number of allowable uses of the states' CCDBG quality set aside in recognition of the need to both mandate and fund quality improvement. However, many believe that additional funding is needed to support further quality improvement while maintaining overall access.

Child Care Subsidies and Outcomes

Child care access through subsidized child care consistently associates in the literature with a range of parental, especially maternal, outcomes, including increased investment in human capital, increased labor force participation and employment, shorter spells of unemployment, and more sustained periods of employment among low-income women who are the targets of the subsidies. Further, expansion of subsidy programs through increased funding or higher reimbursement rates at the state level are correlated with higher parental employment probabilities.

The evidence on the impact of subsidy use on child outcomes is less definitive. According to a review of the child care subsidy literature prepared by the Office of Planning, Research and Evaluation at the U.S. Department of Health and Human Services' Administration for Children and Families, subsidies have the potential to influence child outcomes directly by changing the quality, quantity, and form of nonparental care, including early childhood education, and indirectly by changing a

family's access to financial resources other than child care. However, a limited number of empirical studies have failed thus far to produce consistent evidence on the true nature of the effect, making this an important area of future inquiry.

A note of caution on interpreting much of the literature assessing the efficacy of child care policy in promoting the dual goals of parental labor force attachment and child well-being is warranted. Correlation between subsidy receipt and outcomes does not guarantee a causal relationship between the two. Specifically, unobserved or unmeasurable factors correlated with both child care access through subsidy use and the outcomes of interest may bias correlational estimates, even when multivariate regression analysis controls for confounding factors through means such as instrumental variables and propensity score matching. Although experimental studies that randomly assign participants to control and treatment groups and then assess outcome differences between treatment and control avoid such problems, such studies are typically regional in scope, limiting their generalizability.

The Future of Child Care Policy and Practice

The idea that child care, and early childhood education and care more generally, can play a role in economic development is beginning to gain ground. The social debate over maternal labor force participation appears to have given way to an acceptance of the inevitability if not the value of working mothers. Nobel laureate James Heckman has identified significant positive social returns to investment in early childhood development. Nonetheless, the United States lags behind much of the developed world in terms of the size and scope of child care policy. Increased focus on access to high-quality early care and education for all children is necessary to close the gap in this regard.

CHILD CARE QUALITY AND YOUNG CHILDREN'S BEHAVIOR

Most young children in the United States attend some form of child care or early childhood education before beginning formal schooling. These settings vary enormously, as do children's experiences in them and outcomes associated with them. For this reason, research and policy communities within early childhood care and education have a strong interest in measuring and documenting child care quality and the outcomes associated with it. This entry focuses on the relationship between child care quality and young children's behavior. First, it provides a brief overview of the definition and measurement of child care quality and of young children's behavioral development. Then, it describes current knowledge about the links between child care quality and young children's behavior.

Child Care Quality

Throughout the United States and beyond, it is quite common for young children to spend significant periods of time in a child care setting. Research on the effects of child care has largely moved beyond asking whether child care itself is good or bad for children. Instead, the focus is now on child care quality. It is understood that child care arrangements vary a great deal in terms of their quality, and so defining and measuring that quality, and linking quality of care with children's outcomes, has become key to understanding the effects of child care.

Child care quality is typically conceptualized into two distinct components. The first is structural quality, which involves aspects of the child care setting that are typically concrete, objectively measurable, and regulable. These characteristics include staff education and training, child-staff ratios, provision of specific materials, and features of the physical facility. The second component is process quality, which involves the interactions between caregivers and children, including instructional and emotional/relational features of those

interactions. Process components of quality are theorized to mediate the relationship between structural quality and children's outcomes. For example, staff who are well-educated in early childhood education are expected to interact with children in more effective and developmentally appropriate ways, leading to better outcomes for the children in their care. As process quality is more proximal to children's development, it would be expected to have a stronger relationship with child outcomes, versus structural quality, and some empirical research has found this to be the case. However, process quality is much more challenging to measure and regulate, compared to structural quality, so policy efforts related to child care quality are typically focused on structural quality characteristics.

These structure-to-process-to-outcome relationships have been found in some, but certainly not all, studies of child care quality. Furthermore, many studies find that aspects of child care quality predict children's outcomes, but the relationships are quite small. Additional work is needed to understand which aspects of quality are truly important, how they are best measured, in which settings and for which populations they matter, and which aspects of child development they predict. An important promising direction involves matching domain-specific measures of quality to domain-specific outcome measures, rather than relying on global indicators of quality. Research continues to delve into these questions.

Studies of child care quality, particularly those using newer, domain-specific observational measures, suggest that child care quality in the United States is commonly poor to mediocre. Furthermore, child care quality is not randomly distributed among children. Children from more advantaged families (higher income, greater maternal education, two parents, more sensitive parenting, etc.) are more likely to experience high-quality child care. Children who are already experiencing the risk factor of poverty are likely to experience the additional risk of low-quality child care. Thus, it is an important research and policy priority to document, understand, and ameliorate the risks associated with low-quality child care.

Young Children's Behavioral Development

Early care and education settings are an important context for the development and expression of children's behavior. Educators and developmental scientists often categorize children's behavior into three domains: externalizing, internalizing, and prosocial behavior. Both externalizing and internalizing behavior are considered to be maladaptive, at least in large amounts. Externalizing behavior is undesirable behavior that is directed outward, toward the world around the child. Examples include aggression in its many forms (e.g., physical, verbal, relational), hyperactivity, and oppositional or noncompliant behavior. Internalizing behavior is undesirable behavior that is directed inward, toward the child himself or herself. Examples include depression, social withdrawal, and anxiety. In contrast, prosocial behavior refers to a desirable category of behaviors that benefit others and enhance social relationships. Examples include helping, sharing, cooperating, and comforting.

A general pattern of children's behavioral development over time involves an increase in the ability to control impulses and to behave with intention. Thus, externalizing behavior, which is sometimes also labeled as undercontrolled behavior, tends to decrease as children age. In contrast, internalizing behavior, which is sometimes described as overcontrolled behavior, tends to increase with age, at least for some children. Similarly, prosocial behavior depends on some level of intentional control and becomes more frequent with age.

Beyond these general developmental patterns, a number of other factors appear to influence children's tendency to behave in externalizing, internalizing, or prosocial ways. Boys are more likely to display externalizing behaviors, whereas internalizing and prosocial behaviors are more common in girls. Environmental influences, such as parenting, economic and cultural resources, and neighborhood violence, are also important. Child care is an important environmental context for many young children, and so child care quality can be expected to have some relationship to behavioral development.

The Association Between Child Care Quality and Behavior

Research on child care experiences as a predictor of children's behavioral development has generally included three characteristics of child care: the quality, the amount, and the type. Although the focus here is on child care quality, it is useful first to give a brief overview comparing the evidence related to these three characteristics of child care. The amount of child care experienced (generally measured as hours per week or sometimes as age of onset) has been consistently associated with increased externalizing behaviors. Exposure to center-based child care (as opposed to home-based child care) has also sometimes been linked to behavior problems. Although there is not complete agreement on the relative importance of these factors, as research on child care quality becomes more extensive and more sophisticated, the balance of evidence suggests that child care quality is a more important predictor of children's behavioral development than is the amount or type of child care experienced.

In general, high-quality child care is associated with children's adaptive behavioral development. The most extensive research has been done in the United States, but similar findings have also been found in studies based around the world, including Australia and Sweden. Behavioral outcomes that have been linked to high-quality child care include prosocial behavior, compliance, social skills, positive peer relationships, and attention regulation. High-quality child care has also been linked to fewer behavior problems, particularly externalizing behaviors, and less conflictual relationships with teachers. Most studies examine children's behavior during child care or in the first few years following child care. However, child care quality effects on behavior have been found to last as far as age 15, with high-quality child care predicting fewer externalizing behaviors in adolescence.

Results vary based on how child care quality is measured. Typically, global measures of quality are less likely to predict children's behavior than are more narrow, specific measures of quality. However, those specific measures need not always

be obviously social-emotional in content. Both socially oriented measures of quality (e.g., caregiving quality) and more instructionally oriented measures of quality (e.g., language-reasoning quality, instructional support) have been associated with children's behavioral outcomes. Process measures of quality (e.g., relationship quality) are more often associated with behavioral outcomes than structural measures are, but structural measures of quality sometimes predict behavior as well. Examples include teacher-child ratio and group size. Margaret Burchinal and colleagues have investigated quality thresholds and found some evidence that child care quality best predicts children's behavioral outcomes only when the quality reaches a minimum level of acceptability.

The association between child care quality and children's behavioral outcomes is most often described as small to moderate in terms of effect size. As a group, home- and family-related factors are generally more powerful predictors of children's behavior than are child care factors. Sometimes, when home and family variables are included in the same model, the child care quality variables no longer retain predictive power. This may be because the quality of children's child care experience is related to home and family factors that influence child care access and selection.

Many researchers have investigated whether child care quality is a more important factor for children who are at risk due to home and family background characteristics such as poverty, parenting stress, and unsafe neighborhoods. Research findings have been mixed, but some evidence suggests that high-quality child care can have a compensatory effect. In other words, exposure to high-quality child care may be protective for at-risk children, helping to prevent poorer behavioral outcomes. Similarly, some research has described a double jeopardy effect such that children who experience low-quality environments both at home and at child care have poorer behavioral outcomes than children who experience just one of those conditions.

Some research suggests that the behavioral development of children with certain individual

characteristics is also particularly likely to be influenced by child care quality. Boys, African American children, and children with negative temperaments seem to be differentially affected by child care quality, such that high-quality child care has a stronger positive impact, and low-quality child care a stronger negative impact, on their behavior in early and middle childhood. In adolescence, evidence suggests a diathesis-stress pattern, such that children with negative temperaments have more externalizing behaviors if they experienced poor-quality child care, but they don't have fewer externalizing behaviors if they experienced high-quality child care. Research additionally suggests that a specific genetic marker indicates increased susceptibility to child care quality effects in the prediction of behavior.

In conclusion, child care quality does appear to predict young children's behavior. The overall relationships are fairly small in magnitude, but the association may be especially important for certain populations of children.

CHILD DEVELOPMENT AND EARLY CHILDHOOD EDUCATION

Child development describes the patterns and progress of human development from conception to adolescence. The changes that happen during this period are profound, rapid, and so complex that it is difficult to talk about them all holistically. Therefore, describing how children develop is usually broken into categories or smaller systems. These smaller systems are called domains. The three major developmental domains are physical, social, and cognitive.

Based on nearly a century of careful study, researchers have documented overarching patterns across these domains. Given that the patterns of change occur over time, it is thought that these changes represent normative development. As children mature, the ability or emergence of new skills is sometime referred to as *milestones*.

Major developments, such as beginning to walk or beginning to talk, are called milestones. Normative or typical development occurs when the expected milestones are reached in the expected order within the expected time range. Therefore, another way that child development is sometimes discussed is to describe what babies and children are like at various ages or stages.

Research from the fields of medicine, anthropology, psychology, and sociology make it clear that the environment and context within which a child develops interact with the child's inherited biology to shape the child's development. Because of the interaction between the genes a child inherits from his or her parents (nature) and the context of development or the environment of development (nurture), the individual patterns of development and the exact timing are unique to every individual. That is why a combination of information on domains and ages and stages of development are useful in considering how to best support a child's development. And while it aids in the discussion of what develops to break apart development by domain or time, child development must be understood holistically with an understanding the child is growing and changing across many different domains.

This entry first reviews the domains and stages of development, discusses major child development theories and theorists, and gives an overview of the developmental principles considered important for early childhood programs. It then discusses the importance of child development information in supporting the development of children who are at risk or who have a disability or delay, as well as the limitations of current knowledge about child development.

Domains of Development

There are three major developmental domains—physical, social (or social and emotional), and cognitive. In addition to these major domains, there are many subdomains that are also considered very important for development. These subdomains are both embedded in and overlap with one or more of the major domains. For instance,

language development is a subdomain that overlaps with the physical and cognitive domains but is also connected to the social-emotional domain. Likewise, because the changes that happen in each of the developmental domains are dependent on and influenced by the changes that are happening in the other domains, development is irreducible and can only be understood as the development of the whole child. However, because of the amount of change that takes place and the complex nature of all that is changing, a domain approach to discussing and thinking about development is often useful. The following is a brief overview of the three major developmental domains of child development with examples of the sort of subdomains considered within each.

Physical Development

The most widely studied of all the developmental domains is physical development. A child's physical development can be observed starting at conception. Even prenatally, children's biological development is tracked in terms of length (height) and weight and physical activity (kick counts), and their nutritional needs are addressed through prenatal diet. Once a child is born, he or she is weighed and measured, and this information becomes part of the health record that will follow him or her throughout life. Physical development also includes physical differences between boys and girls, especially with the onset of puberty toward the end of the child development period.

Sensory development and motor skill development are two of the subdomains studied under the domain of physical development. Children's ability to hear, taste, and touch begins to develop in utero, before they are born. Visual capacity does not begin to develop until after children are born and they begin to use the small muscles in their eyes needed to focus. Motor development includes development of both large (sometimes called gross) and small (sometimes called fine) motor skills. Gross motor skills include learning to control and use the large muscles in the legs and arms. Fine motor skills include abilities to move hands and fingers, feet and toes.

Brain Development

While the brain is technically a physical organ, how it develops is highly influenced by the environment. A baby's brain development begins at conception and is highly sensitive to environmental conditions. Everything a pregnant woman eats, drinks, and breathes affects the developing baby's brain. Brain tissue is made up of neurons and glial cells. The neurons are the cells that control what we consider brain activity (movement, thinking, feeling, speaking). Neurons are formed prenatally. Once a baby is born, connections between neurons develop. These connections are called synapses and they shape the brain and how it functions.

The ability of the brain to change and shape itself is called brain plasticity. Neurotransmitters are chemicals released by neurons that send signals across the synapses allowing the neurons to communicate with each other and form networks. The synaptic links between neurons are strengthened, as neurons are stimulated and synaptic connection used. It is believed that there are several hundred different types of neurotransmitters. Neurotransmitters are produced in response to many things, including environmental stimulation. For instance, when a person is frightened or scared, norepinephrine is released allowing for quick movements—the fight-or-flight ability. Ultimately the experiences one has build brain function and structure by strengthening neural connections. How these connections operate is influenced by the neurotransmitters that are also influenced by experiences.

Social Development

Social or social-emotional development addresses how children relate to and form relationships with other people. For instance, all babies have a need to form an attachment relationship with their primary caregiver(s). For many babies their primary caregiver is their mother. Babies will also form attachment relationships with other adults who regularly care for and nurture them. Depending on the family and culture, other caregivers could be fathers, grandmothers, or child care providers.

As babies grow older, the attachment relationship they form with their caregiver(s) will shape the way that the child develops relationships. A caregiver who provides warm and responsive caregiving can help soothe babies when they are afraid or distressed. This is important because high levels of fear or sadness over a prolonged period of time can have negative effects on brain development by exposing the brain to the chemicals in stress hormones and neurotransmitters. Research from children who have been abused or neglected indicates that they have social-emotional and cognitive challenges later in life. It is believed that many of the emotional and behavioral issues brought about by abuse and neglect stem from the changes in brain chemistry and functioning brought on by this toxic stress.

The study of emotions and emotional regulation also falls within this domain. Researchers have generally agreed that there are six globally recognized major emotions: sadness, happiness, anger, disgust surprise, and fear. More recently these six have been narrowed to as few as four, with anger/disgust and surprise/fear being biologically blended together with only socially constructed differences. Although these four emotions are universal, culture dictates how they are understood.

The study of temperament is a subdomain of social development. Temperament is an inborn biological feature that influences how the child behaves. Various researchers have studied temperament and divided it into several different dimensions; in early childhood these dimensions include activity level, sensitivity to the environment, regularity in bodily functions (sleep, bowel movements, hunger), and initial reaction to new situations. Initially researchers were interested in trying to help children who were considered shy, that is, those who were slow to warm up and had difficulty adapting to new situations because they were unwilling to explore. More recently there has been interest in learning how to support those children with low persistence and high activity levels, as these temperaments are associated with attentional issues.

Understanding friendships and peer relationships is an important subdomain. As children grow

older and begin to interact with other children and develop relationships with peers and other caregivers, these relationships will be shaped both by the child's own personality and the social context. The ability to recognize other people's emotions and to develop empathy for others is an important social milestone.

The social-emotional realm also addresses children's ability to manage their own emotions and to develop the skills of behavior management and executive functioning. Managing one's own emotions is related to executive functioning, as one must be able to refrain from lashing out with hitting or biting when angry. However, executive functioning is also associated with being able to wait for a reward, such as a marshmallow, if waiting means that you will be able to get more of the reward. Executive functioning is also related to persistence and the ability to stick with a task even if it is unpleasant. Persistence and attention are critically necessary to support development in the third domain, cognitive development.

Cognitive Development

Cognitive development is described as the child's developing ability to think and learn. Cognitive development is dependent on a child's needs being met both physically and social-emotionally. Among the subdomains included under cognitive development and that are assessed in order to measure cognitive ability are language development, memory development, and problem-solving ability.

Cognitive ability is often called intelligence. Measuring intelligence by determining a person's intelligence quotient or IQ score started very early in the study of psychology. In the beginning, intelligence was limited to measuring verbal, computational, and memory skills. However, there are many problems with measuring cognitive capacity in this way, mainly because tests such as these assume that everyone is exposed to the same information and language. Clearly a person can be very intelligent and not speak English, a problem if the intelligence test is in English. It is for this reason that it has been difficult to accurately measure

cognitive abilities in very young children, because they cannot yet communicate in a way that allows them to be tested. Likewise, many now have a more broad conception of intelligence that incorporates the idea of multiple intelligences, including abilities such as kinesthetic (movement), visual-spatial, and musical-rhythmic.

Within the domain of cognitive development, much of the academically related abilities such as mathematics, science, and literacy appear. While literacy skills are often considered an indication of cognitive skills, it is clear to see that literacy is also influenced by sensory development—both sight and hearing, because the foundation of literacy is language development. And while language development is often considered a subdomain of cognitive development, speech and hearing are usually placed in the realm of the physical developmental domain. Further, language is learned in relationships and is influenced by social context and experiences.

Because the changes that happen in each of the developmental domains are dependent on and influenced by the changes that are happening in the other domains, development is irreducible and can only be understood as the development of the whole child. That is why an age-based understanding of child development is useful.

Stages and Ages of Child Development

The field of child development spans prenatal development to age 12, at which point children are considered adolescents. Embedded within this age span are the early childhood years. It is widely agreed that early childhood encompasses the years from birth through age 8. Early childhood education addresses the learning needs of children before they enter formal primary grades. The age at which children begin first grade varies by country, with children starting as young as 5 years old in some countries and in others starting as late as 7 years old.

The age ranges given for children acquiring various abilities represent normative development; not all children will fit within these ranges. Even within the early childhood time frame there are

smaller age ranges that are given special consideration in the field of early childhood education. The age range from birth to 5 years old is often divided into programs for infants and toddlers and programs for 3- to 5-year-old preschoolers. In the United States the 3- to 5-year-old age range is often referred to as preschool, with kindergarten starting somewhere between the fifth and sixth birthdays. However, different countries have widely varying ages at which children begin formal schooling. Further, these ages and programming change over time. For instance, in the United States, with the emergence of prekindergarten programs for 4-year-olds, prekindergarten may at some point be considered the transition to formal education.

During the infant and toddler stage, children typically learn to roll over and crawl. Typically somewhere between 9 and 12 months, babies will take their first step and eventually walk (toddle) by around 18 months. They usually start to say proto-words (“dada,” “mama”) anywhere between 9 and 12 months, and they usually will have said their first word by 12 months. During the first few months they have established an attachment relationship with their primary caregiver(s), and they will seek their caregiver at times of fear or uncertainty once they start exploring the world through crawling and later walking. During this period babies go from a liquid diet, to beginning to eat solid foods, to beginning to feed themselves.

During the 3- to 5-year-old stage, children learn to manipulate smaller objects with their fingers and develop the ability to hop and skip. They begin to notice the symbols and signs in their environment and will be able to “read” common symbols. Preschool children begin to form friendships with same-age peers they see and interact with regularly.

During the 5- to 8-year-old stage, children develop and then refine the ability to read and write. By the end of the early childhood stage, a child must go from learning to read to the ability to read to learn. They develop a wider range of friendships. They are able to toilet, groom, and eat independently. They can run, throw, and catch balls, and they begin to develop the skills of various sports. They enjoy games with rules. Toward

the end of this period, children begin to develop the ability for abstract thinking and more sophisticated reasoning. They can spend more time on tasks with multiple steps that extend over longer periods.

The emergence of developmental skills usually takes place within a general age range. Children achieving a milestone anywhere within the normative ranges are considered on track for typical development. For some milestones, the range is very tight; for example, birth usually occurs after 9 months of gestation. For other milestones the range covers several years. For instance, the typical and normative onset of menarche in girls ranges over a 2-year span and gets younger with increased access to nutrition and health care.

To determine the level of functioning of a child compared to what are established age-related abilities, screenings and assessments are used. Screenings are used as a quick check-in to determine if a child is or is not on track with his or her development. Assessments are used to hone in and determine at a much finer grained level what a child is able to do compared to same-age peers. If a screening tool raises a concern, an assessment is then used to determine more specific issues and concerns. Both assessments and screenings are grounded in the developmental data that have been gathered for well over a hundred years on children's developmental abilities.

Sometimes children have delays in development not because of a biological or genetic condition but because the environment is such that it poses a threat to development. In some cases the environment does not offer support for development, and in other cases the environment actually harms development. In these cases children are said to be at risk for developmental delays or damage. In this way the term *at risk* signifies that the delays a child will experience are due in large part to the environment they are developing in and are not solely because they have a genetic or physical challenge. Often this designation is reserved for children who do not have an identified challenge or delay but for whom there are environmental factors known to contribute to less optimal outcomes. Among these

factors are living in poverty, having parents (especially mothers) with mental health issues, and having highly chaotic and inconsistent routines or living arrangements. Research has shown that as the number of risk factors increases, the likelihood that a child will experience a delay increases.

Child Development in Early Childhood Education

Over the years, children's programming and, in some cases, curricular approaches have been developed based on theories, beliefs, and research on child development. While early care and education programs are designed to support learning, in the same way that elementary schools support learning, what this looks like in early childhood programs varies greatly from what is done with older children.

Historical Roots

Guidance on how to care for and teach children dates back to antiquity. Plato and Aristotle offered guidance for children's education, as did Confucius in China. In India there are ancient texts devoted to pediatric medical care. Since antiquity, adults have been concerned with preparing children to take on the tasks of adulthood. Ideas on what influences a child's development have swung between a belief that the child was born with a set of capacities that could be shaped and taught but not changed, to the belief that a child could be shaped into being anything by the adults around him or her.

It was not until the late 1800s that childhood was seen as a special time in life that needed attention and study. One of the reasons for this was based in the work of evolutionary theorists such as Robert Chambers and Charles Darwin. Notions of progress and universal laws driving development were very appealing to intellectuals of the time. As a part of this interest, observations of children and how they grew emerged. The interest in development corresponded with the emergence of the field of psychology in the 1800s.

Psychosocial Development

Some of the early pioneers in psychology contributed to the field of child development. Sigmund Freud's observations on human development led to his stage theory of psychological development. Erik Erikson built on this work and developed a stage theory of emotional development with a set of developmental crises that must be resolved in order to continue to progress.

John Watson felt that parenting could shape behavior. Watson, and later B. F. Skinner, keeping with the blank slate idea, theorized that learning was externally controlled through punishments or rewards. Rewards are also called reinforcements and are widely used in programming. An example is giving a child a sticker when he or she has used the potty.

Cognitive Development and Constructivism

However, other psychologists felt that it was not just external inputs that shaped children's development, but children themselves were also responsible for their learning. This perspective is called constructivism, meaning that children construct their own knowledge. Although both Jean Piaget and Lev Vygotsky are considered constructivists, their views on the order of construction and how knowledge is constructed differ widely. Piaget began studying children because he was interested in the mistakes that they made on intelligence tests. He developed a view that the reason that children do not do as well as adults on intelligence tests was not because they were not as intelligent as adults, but because they thought about things differently from adults. Piaget began to ask children questions and study how they understood information, developing from this a theory of stages of children's cognitive development. Piaget hypothesized that development must come first and that the child's stage of development influenced the way that the child would then construct his or her own new knowledge or understanding. Vygotsky felt that knowledge, gained through interactions with adults, peers, and cultural tools (e.g., books), was the driver of development.

Bioecological Model

In the 1960s and 1970s theorists began to include an increasing awareness of social and environmental influences on development. In this period, Urie Bronfenbrenner articulated a bioecological theory of child development. The theory is based on the foundation that context shapes, and can also be shaped by, development. From the Vygotskian tradition that included the works of Kurt Lewin and James and Eleanor Gibson, the theory suggests that development is driven by interactions between the individual and the individual's social and physical environment. The ecological model of development is still widely used today as a framework for understanding the influences of social and environmental features on physical, social, and cognitive development. The pervasive and devastating impact of violence, war, poverty, abuse, and neglect on children's development are all explained by this theory. So, too, are the influences of public policy. The ecological model includes a nested set of systems from the microsystem, such as a family, the child care center, or the school, to the macrosystem, which includes culture and politics that shape policies.

Other important innovators and theorists whose understanding of child development became the basis for programming include Friedrich Froebel, John Dewey, and Maria Montessori. Froebel established the first kindergarten based on a set of activities designed to meet the developmental needs of the young child. Dewey believed in democratic education and that learning should be grounded in real and purposeful work. Montessori's background as a physician and her observations of children led her to develop a set of materials and activities and programming ultimately leading to the Montessori approach to education.

Importance of Child Development for Early Childhood Education

Understanding what develops, in what sequence, and how to support its development is the basis for the concept of developmentally appropriate practice (DAP). According to the National Association

for the Education of Young Children (NAEYC), a firm grounding in developmental knowledge is critical for early educators. NAEYC's position statement on DAP describes principles of child development that must inform practices and programming for young children. The principles in the DAP statement can be summed up as follows:

- All domains of development are important and they are all mutually influential. For instance, in the subdomain of language development, physical development is necessary because in order to speak, the ability to control mouth and tongue movements and auditory (hearing) ability are critical. Further cognitive development is evidenced in understanding words and remembering what they mean, and one must have relationships with people and things that promote communication. Because of this, children benefit from having a wide range of experiences that challenge all their developmental domains in order to maximize learning. Hearing stories, singing songs, clapping rhymes, looking at books, and experimenting with writing are some of the many experiences that bolster preschool children's language development.

- Much of development follows a predictable pattern with later skills and abilities building on those already established. Thus, development proceeds from the simple to the more complex and sophisticated. For instance, most children learn to crawl, creep, or scoot before they learn to walk. Because of this, early experience matters a great deal and there are optimal periods for learning. This is closely related to a notion of critical periods, times when if an experience does not happen, a child's development will be altered. We know that if children cannot hear, they will not learn to speak and that from birth to 6 months children will learn to ignore sounds of words that they do not hear in their language. As researchers developed an understanding of age-based abilities, it became clear that there are experiences in certain areas that children need in order to develop in an expected fashion. These are known as critical or sensitive periods.

The most extreme example of this is vision. If a baby is deprived of sight, the visual cortex will not develop connections with the brain and the child will never see. If a child cannot hear, it will be difficult for him or her to learn how to speak. However, unlike sight, if a child's hearing is repaired, for example, through the use of a cochlear implant, the child will acquire verbal capacity if he or she is exposed to a rich verbal environment. Some of the experiences that children have early in life have profound effects on their development years later. For instance, attachment, usually thought of in the domain of social development, is associated with children's school success years later.

- Development proceeds at varying rates from child to child and is uneven across abilities. For instance, although most children are walking and talking by around 12 months, there is a wide range in these ages, even for typically developing children. Some children start walking as early as 9 months and some do not take their first step until 14 months. Usually a child does not start to take steps and to talk at exactly the same time; one skill usually precedes the other.

- Development is the interaction between a child's genetic makeup and the interactions he or she has with the environment and the people in it. In this way development is influenced by culture and context. Children's motivation, persistence, initiative, and creativity are shaped by their experiences. The languages spoken around a child influence the language the child learns and how he or she learns to communicate. For instance, the Native American Pima tribe has a genetic susceptibility to diabetes. However, it is the substitution of traditional food and agricultural practices that has caused the diabetic epidemic among the Pima in Arizona; in contrast, those who live in Mexico and practice traditional agriculture and eat traditional foods are not afflicted at higher rates than the population at large.

- Relationships are critical to children's survival. Children's development is maximized when they have stable loving relationships with adults who care for them and when they are supported in

developing friendships. Children must have adults who talk to them and respond when they communicate in order for language to grow.

- Play is an important activity because it supports cognitive, social, emotional, and physical development. Pretending to have a tea party or to command a pirate ship stretches cognitive skills and provides opportunities for language use beyond the utilitarian or mundane.

- Children are active participants in driving their own development. They need challenges where their skills are pushed to grow, but they also need a chance to practice newly acquired skills so that they can develop. Children are active explorers; even on cave drawings in Europe there are marks made by a 4-year-old girl in every room, showing how at the dawn of civilizations children were actively exploring ways to communicate. We see that same push toward creativity and meaning making in 4-year-olds, who, once they learn to write their name, will write it over and over again.

- If a child is encouraged to speak, is listened and responded to in a loving and nurturing way, and given experiences that invite communication, that child will develop a sense of himself or herself as a competent communicator with the courage to take risks and explore the world of language.

These guidelines do not really instruct educators in what to teach; rather, they guide educators in how to teach. In this way DAP is not a curriculum (what is taught) but a pedagogy (how it is taught).

The importance of understanding the principles of child development for the field of early childhood education is based on two major factors: (1) The developmental needs and capacities of a child must be understood in order to plan appropriately for the child, and (2) experience shapes development. The demands of serving both sets of developmental needs—the needs the child has in the moment based on his or her abilities and skills and the need to support the child who is to come—make early childhood programming particularly fluid and dynamic.

The variation in the abilities children have within each developmental domain in the span from birth to school age means that very different types of programming must be offered to the different ages. For instance, small beads and other manipulatives that are appropriate for use by 4-year-olds would be a choking hazard for a 4-month-old. It is also critically important to understand the importance of experiences and relationships to children's development. When early care and education programs are able to support children's physical development, caregivers and teachers are able to provide warm and responsive care and build relationships with children, and provide activities and learning opportunities for children based on what they can currently do, as well as provide activities that are a bit challenging and that build the skills the child will need to meet their next milestone, children's development is supported.

Because effective teaching requires the ability to notice when each child is ready to practice a skill that has just been mastered and when to introduce new materials that will foster the development of new skills for each child, collecting and utilizing assessment information on children in early care and education programs is an essential role for early childhood professionals.

Nota Bene

While an understanding of child development is critical to early childhood education, one must understand how much is known about child development and the limitations of this information. Much of the research that is the basis for child developmental theory and knowledge is from Western samples drawn from majority cultures. Because child development stresses the interaction between the developing person and the environment and culture, more information and data on typical normative development from other cultures is vital. Likewise, the information from work in the medical field and genomics makes it clear that at some point in the future we will be able to better differentiate the impacts of this person–environment interaction and its outcomes on

development. But for now it is clear that optimizing conditions physically, socially, and cognitively is the best approach to supporting the development of young children.

CHILD DEVELOPMENT LABORATORY SCHOOLS

Child development laboratory schools are a particular type of laboratory school with a slightly different history and purpose than, perhaps, the laboratory schools that existed at places such as the University of Chicago. Child development laboratory schools arose in the early part of the 20th century out of a need for scholars to engage in deliberate, scientific child study that would contribute to the development of social policy. Over the past hundred years, child development laboratory schools have evolved in structure, function, and auspices. These programs have often struggled in more recent years with justifying their existence and expense, and many that have survived have

redefined themselves. This entry provides a brief history of these programs, describes the current status of child development laboratory programs, and explores future potential roles for these programs.

Definitions

For the purpose of this discussion, child development laboratory schools are defined as those programs housed within a university setting (with or without specific departmental affiliation) that have as their goal a three-part mission of research, service, and professional preparation of students. These three missions may be equal, or one or more may have higher priority in the institution, but all three are present. In many cases, child development laboratory schools have a very long history within the institution, many beginning in the 1920s, often tied to home economics, or psychology, or education, or deliberately interdisciplinary. However, the primary focus at the inception and at present is child study and child development. The importance of these programs continues to be that they are places of scholarly study of children, learning, families, and service delivery. As such, knowledge of child development laboratory schools adds to our understanding of early childhood development, learning, and services.

History and Context

Charles Darwin's work in the 19th century spawned an era of scientific study of human evolution. People such as G. Stanley Hall pioneered such study in the area of child growth and development at Clark University, establishing a center for research and writing about child development. Organizations such as the Child Study Organization and the Committee on Child Development, within the National Research Council, legitimized the empirical study of child development. These entities came about so that scholars could document child growth and development and better understand the field in order to inform education, medicine, and policy.

Among the early movers and shakers in the field of child study, Lawrence K. Frank stands out in the history of child development laboratory schools. An economist, Frank had volunteered with the Bureau of Social Research in New York and was eventually hired by the Laura Spelman Rockefeller Memorial (LSRM) in the early 1920s to oversee the distribution of funds to universities for the purpose of child study. The LSRM was interested in funding research centers that would engage in the study of child development and prepare others to do the same. Frank's vision went beyond the basic funding process. He saw the funding mission as a way to influence a broader social movement by influencing others to improve the lives of children and families.

Frank had some specific criteria in mind for those institutions hoping to receive funds. He believed that the research centers should be multidisciplinary rather than housed in one department, perhaps bringing together psychology, social work, medicine, and education. He also preferred that the institutions be land grant designated because these already had a mission of outreach to the community. In the end, LSRM established funding at institutions such as the University of Minnesota Institute of Child Welfare, the University of California at Berkeley Institute of Child Welfare, Yale Child Study Center, the Iowa Child Welfare Research Station, and Columbia Teachers College Child Study Center. Other child study centers also emerged at about the same time at Bank Street College of Education and Merrill-Palmer Institute, now the Merrill Palmer Skillman Institute. These institutes looked at both child development and aspects of child life. Frank's hope always was that the empirical work done in the laboratories would contribute to the development of policy regarding children and families.

Other child development laboratory programs were funded by different sources. A private benefactor, though not under the auspices of LSRM, funded the Merrill-Palmer Institute, for the original purpose of motherhood training. The primary mission of the institute was to train women to teach in early childhood programs. This laboratory

school employed some of the country's top child development and education researchers before it closed in 1980.

The Bureau of Educational Research in New York City was founded at about the same time through non-LSRM funds, later becoming the Bank Street College of Education. The faculty and researchers involved at Bank Street also contributed to the growing knowledge about child development and instructional practices. The school has evolved and survived over the years to become a leader in early childhood education.

The Yale Child Study Center, an LSRM-funded site, was the home of Arnold Gesell in the early 1900s. Gesell engaged in research that documented normative development of young children. He employed innovative research methods to film his subjects and chronicle their development over time. A guidance nursery was added for the purpose of diagnostic and therapeutic intervention. Unlike the other LSRM-funded sites, the Yale Child Study Center was affiliated with the university's medical school. Changes in leadership eventually influenced the site to become more psychoanalytic in focus, eventually as a full-service psychiatric center for children.

The work of these original LSRM-funded centers, and of the centers funded by other sources, has made profound and long-reaching impacts on our knowledge and understanding of children, families, and life span development. Many of them are still operating today, although with different missions and foci. For instance, the University of California at Berkeley started with a child guidance study just before the Great Depression began. These individuals were studied over decades, looking at their development over time, eventually becoming a serendipitous chronicle of the impact of the Great Depression on children and families long term. The Institute of Child Welfare became the Institute of Human Development. Other centers changed their broader focus to more specific specialization. In all cases, this history is the foundation of child development laboratory schools today.

Current Status of Child Development Laboratory Programs

Over the past 20 years, child development laboratory schools at many institutions have struggled to survive. In difficult times, many universities have examined the cost-effectiveness of child development laboratory programs. Organizations such as the National Organization of Child Development Laboratory Schools have provided a forum for directors and faculty at these sites to provide support and assurance to those struggling to remain viable on their campuses. Conversations among laboratory school faculty revolve around the importance of preserving laboratory schools as places of innovation in research, service, and professional preparation.

In some cases, preserving laboratory schools means revising the way service is provided. Some laboratory schools that had been engaged in traditional programs that provided services to families part-day have become full-day programs; some laboratory schools that were seen as pools of subjects for psychological research have cultivated research that examines aspects such as pedagogical practices; and some of those that have served only university faculty have expanded their reach to serve community children and families. In some cases, the three-part mission has shifted so that professional preparation becomes the first priority and research takes a less important place in the three-part mission. For some, external funding for research has helped them maintain their empirical mission. Certainly, there has been a drift away from Frank's, perhaps unrealistic, expectation that child development laboratory schools have a direct line of influence on social policy. However, these sites continue to be places of child study.

Future Trends

Through necessity, and because there is a belief that child development laboratory schools serve an important function on university campuses, several innovative trends are occurring. These trends locate the work of various child development

laboratory schools in different categories of activity: laboratories of practice, laboratories of service, laboratories of professional preparation, and laboratories for research.

Laboratories of Practice

Several child development laboratory schools have shifted their empirical inquiry to a study of practice in their classrooms. For instance, the laboratory schools at Kent State University and South Dakota State University have engaged in collaborative inquiry. Both groups of faculty have been studying the Reggio Emilia approach and have developed Reggio-inspired practices. They define themselves as schools of inquiry. They have, through technology, participated in book discussions and shared research on practice—in particular, on the process of documenting children's learning. Although their contexts are quite different, they have found growth in their thinking and practices as a result of this long-distance collaboration. In common, they have turned their research function inward, focusing on their own practices rather than serving as a subject pool for other researchers.

Laboratories of Service

The notion of child development laboratory schools as places housed within the university has been challenged by faculty at several universities as they become involved in community programs as researchers and evaluators. For instance, faculty at the University of Oklahoma have developed a healthy research agenda around a community Head Start partnership. Beginning first as evaluators of the program, they have become involved in research related to the outcomes but thoroughly connected with the partnership. It serves the purpose of providing a context that involves research and service and has the benefit of being delivered in multiple sites across the country, allowing for cross-site comparisons. Such revisioning of the laboratory concept allows for research that has direct service implications.

Laboratories of Professional Preparation

One of the long-standing criticisms of child development laboratory schools is the exclusivity of service. In many cases, the participants in the program are children of faculty and staff, often not a very diverse group. Consequently, criticisms focus on the ability of research done in a laboratory setting to be generalizable to a broader population. In some instances, laboratories have revised their admissions policies to be more inclusive, serving the community at large. In one case, a laboratory chose to partner with a local school district in order to serve 3-year-old children with special needs who were not being served in the community. This arrangement served both the university and the school district. It provided the university early childhood program with a setting for professional preparation where college students could work in an actual inclusive setting, and it provided service to previously unserved children and families. The overall potential for professional preparation is unlimited.

Laboratories of Research

The most traditional function of the child development laboratory school has been to conduct research. However, rather than serving as sites for recruitment of subjects, laboratories have collaborated with researchers to develop studies that are embedded in the practices of the school. For instance, the University of Illinois Child Development Laboratory director has been a co-investigator involved in a study of nutrition and its relationship to childhood obesity within the classroom at the school. Rather than being an observer of the research, he has served as an active participant.

Potential for the Future

Since the beginning of child development laboratory schools almost a hundred years ago, there has been much change in what is known, what we want to know, and how we come to know it. The child development laboratory school remains a

viable option to do research, develop professionals, and provide innovative service to families and children. What has changed is the way these schools do all three parts of the mission. The potential for laboratory programs seems endless given the possibility of communicating quickly, across space, and across time. For instance, technology allows programs to collaborate on innovations in teaching across university sites. It also allows programs to study a similar social issue across multiple sites and contexts, sharing data and maximizing their empirical design (e.g., by collecting more data). There is potential for partnering with service providers to expand the research conducted at university sites and study the results across different populations.

CHILD OBSERVATION RECORD

The Child Observation Record (COR) is an assessment tool that teachers and other observers use to observe, record, and score young children's development. It was originally designed for use with the HighScope curriculum, but it can be used with any child development curriculum. The instrument, revised in 2013 and renamed COR Advantage, is comprised of 36 items in nine categories or domains of early learning. Using COR Advantage, the assessor observes a child's behavior to identify developmentally significant activities and categorize these activities in the relevant domain and item of development and the child's developmental level on the item. The instrument briefly describes each domain and item. To help

assessors score children's performance with the instrument validly and reliably, it provides illustrative examples of each developmental level.

HighScope Educational Research Foundation developed preschool and infant-toddler versions of the COR in 2003, then expanded and consolidated them into the 2013 version, which spans birth through kindergarten. Each version has evidence of reliability and validity. COR Advantage focuses on children's spontaneous activities throughout the program day rather than their performance on tests, thereby permitting a broader and more authentic perspective on their development.

Mapping a Child's Development

Assessors using COR Advantage begin by taking notes (anecdotes) of their observations of children's behavior in the program over several weeks to several months. Each note is dated and identifies the child who acts, what the child does (including any adults or other children involved), and when and where the child does it. Each note is then scored according to its content domain, the relevant item within that category, and the child's developmental level on an 8-point scale. An anecdote may be scored in more than one category. For example, an anecdote for Lucas might read: "In the block area on February 17, Lucas, Nera, and Katelyn built a castle with large blocks; Lucas suggested they build a bridge and a tower, asked Katelyn to hand him some additional blocks, and showed her where to put them." This example shows Lucas's development in at least two domains:

1. In the social and emotional development domain, on building relationships with other children (item F), he played collaboratively with two or more other children by contributing ideas and/or incorporating ideas from other children into their play (level 5).
2. In the creative arts domain, on pretend play (item AA), he played with two or more children, stepping out of the pretend play to give directions to another person (level 5).

Teachers typically complete COR Advantage three times in a school year—fall, winter, and spring—although it can be completed more or less often depending on the program's schedule and reporting requirements. Repeated measurement, at least in the fall and spring, are critical to assess children's development over time. Assessment over time renders a measure of children's development, rather than merely their developmental status. It is reasonable to attribute this development over time to the program the child experiences, not merely to advancing age, although this conclusion is strengthened by comparing change scores with those of children from similar backgrounds who did not have comparable program experiences. COR Advantage scores at the end of preschool can also be used to assess a child's readiness to enter kindergarten by benchmarking the child's scores against data collected on other children in that age group. COR Advantage is also useful to assess children with special needs, as developmental progress can be tracked, including with reference to individualized education program (IEP) goals, without being bound by age norms.

The nine domains and 36 items of COR Advantage are as follows.

1. *Approaches to learning*: initiative and planning; problem solving with materials; and reflection
2. *Social and emotional development*: emotions; building relationships with adults; building relationships with other children; community; and conflict resolution
3. *Physical development and health*: gross-motor skills; fine-motor skills, and personal care and healthy behavior
4. *Language, literacy, and communication*: speaking; listening and comprehension; phonological awareness; alphabetic knowledge; reading; book enjoyment and knowledge; and writing
5. *Mathematics*: number and counting; geometry—shapes and spatial awareness; measurement; patterns; and data analysis

6. *Creative arts*: art; music; movement; and pretend play
7. *Science and technology*: observing and classifying; experimenting, predicting, and drawing conclusions; the natural and physical world; and tools and technology
8. *Social studies*: knowledge of self and others; geography; and history
9. *English language learning*: listening to and understanding English; and speaking English. (These items are only for English language learners.)

Versions and Their Reliability and Validity

COR Advantage (2013) is designed to be used with young children from infancy through kindergarten age with each item scored along a developmental continuum. The previous preschool and infant-toddler versions were published in 2003. It was originally published on paper and, soon after, on CD-ROM. As use of the Internet became commonplace throughout the United States and in other countries, the online version became dominant and the previous versions were phased out.

COR Advantage items are consistent with HighScope's multileveled key developmental indicators, the Head Start Child Development and Learning Framework, Common Core State Standards for kindergarten, various state early learning standards, and the guidelines of professional content-specific education organizations. The first draft of the COR Advantage received high ratings from 26 internal and external content and child development experts for its comprehensiveness, feasibility, appropriateness of domains, representativeness of items within each domain, accuracy of developmental scoring progressions, and clarity of descriptions and examples given.

Using 212 videos and vignettes developed by HighScope staff to represent all the levels of development in the nine COR Advantage domains, COR Advantage was field tested with a sample of 71 early childhood teachers from

diverse programs in Michigan in 2012. Item-level difficulties were found to be ordered as expected, teachers did not vary significantly in the ease or severity of their ratings, and the scale functioned as expected. Domains and items required no revisions, but a few levels that did not fit these expectations were revised. Initial online reliability assessment found 85.7% exact agreement on COR Advantage items. These same teachers also completed the COR Advantage in their classrooms, leading to further minor adjustments to the levels and training. Development and assessment of validity and reliability continue at this writing, with plans to use COR Advantage with a nationally representative sample of teachers and children, pending funding.

The Preschool COR used previously was published following studies of its statistical properties when collected by Head Start teachers in a Head Start grantee in 2002. On a 1 to 5 scale, the average total scores were 2.49 in the fall and 3.47 in the spring. Alpha coefficients of overall internal consistency for 32 items were .91 to .94, with domain coefficients ranging from .75 to .88. Correlations between scores for 10 pairs of teachers and assistant teachers were .73 for the total and .69 to .79 for the domains. A confirmatory factor analysis identified four factors that fit these domains. COR total scores correlated as expected (.46 to .52) with the Cognitive Skills Assessment Battery and children's ages (.31) and no significant correlation with gender.

The Infant-Toddler COR was developed in consultation with 38 practicing infant-toddler caregivers. Its statistical properties were studied with 20 caregivers, who observed 50 infants and toddlers (4 to 36 months old) in seven child care centers and one family child care home, following 2 days of training. The alpha coefficients of internal reliability for their scores were .99 for the total and .92 or .93 for the domains. To assess interobserver agreement, 18 of the caregivers worked in 9 pairs to observe 42 children and score them independently. The correlations between the scores of the two groups of pair members were .93 for the total and .83 to .91 for the domains. COR total scores were

correlated .83 or higher with mental and motor age scores on the Bayley Scales of Infant Development on 30 children and remained significantly positive after removing the effect of child's age.

The Position of the COR

As a method of systematic observation, COR Advantage stands in sharp contrast to standardized educational testing, in which individual students are asked by an adult to answer a series of questions or perform a set of tasks, each of which has a "correct" answer. In the observational method, children's spontaneous behavior determines what is assessed. In the standardized measure, the behavior is prescribed by the test procedure. The advantage of standardized educational testing is that it is efficiently administered, and a technology of educational measurement has developed over the past century to support it, including sophisticated mathematical procedures for assessing its reliability and validity. However, it purchases these advantages at the expense of its ecological validity (ability to truly represent a child's ability) and breadth of what it can assess.

The assessment methods employed by COR Advantage are rooted in the systematic procedures of child development research and the daily observations teachers make in order to plan effective educational experiences for young children. Rather than performing on an adult-defined test, students engage in their typical behavior; assessors observe this behavior and draw out its developmental significance. Children are not asked to perform at certain levels of development or difficulty. Rather, they behave as they usually do, and the observer assesses the levels of development at which they are behaving.

Systematic observation has two enormous advantages over standardized educational testing. First, it has higher ecological validity because it does not intrude into the child's environment. A standardized test lacks ecological validity because it temporarily replaces the child's ordinary environment with the artificial test environment. The second advantage of systematic observation

of children's behavior is that it offers a much more comprehensive view of the many dimensions of children's development than does testing. Testing is limited to the knowledge and skills that involve single right answers—for young children, some aspects of literacy, mathematics, social studies, and science. Systematic observation is far more powerful than testing for assessing approaches to learning, social and emotional development, creative arts, and the aspects of literacy, mathematics, social studies, and science that do not involve single right answers, such as oral comprehension, solving applied mathematical problems, appreciating diversity, and applying the scientific method.

Observational assessment has other advantages over tests as well. When conducted by caregivers and teachers, the observations occur in the course of the normal program day, and time does not need to be carved out of the regular routine to conduct testing. The observation notes provide valuable information that allow adults to scaffold (support and gently extend) learning for individual children and for the class as a whole. Moreover, information about a child's development (generally without scores attached) is easily shared with parents, along with examples and strategies for supporting a child's learning at home.

Several other early childhood assessment systems resemble COR Advantage more than they resemble standardized educational tests. One is the Work Sampling System, developed by Sam Meisels and his colleagues. Unlike COR Advantage, it centers on elementary-school-age children rather than younger children, and as its title suggests, it focuses on children's products rather than their behavior. Another is Teaching Strategies Gold, designed for Head Start and other preschool programs. Unlike COR Advantage, which uniquely defines each level within an item, Teaching Strategies Gold defines every other level, leaving it to the assessor's discretion to determine when a child's behavior falls into the undefined middle ground. Both Work Sampling and Gold have some evidence of their reliability and validity.

CHILD-INITIATED LEARNING

Child-initiated learning is learning activity that children initiate themselves, as opposed to learning activity that is initiated and directed by adults. Children plan and select their own activities, and adults participate rather than lead them. Child-initiated learning involves cognitive, social, and physical learning that is within, but desirably near the upper limit of, each child's abilities. It involves the inside-out learning of discovery and thinking about experience and the outside-in learning that comes from interaction with other people. Rather than controlling these activities, adults share control with children.

To support child-initiated learning, adults set up the classroom in learning centers or activity areas and give children time in their daily routine to plan and choose their own activities. Child-initiated learning is widely regarded as a critical component of early childhood education, as indicated, for example, by its role in the description of developmentally appropriate practice by the National Association for the Education of Young Children and the requirement for a balance between teacher-directed and child-initiated activities in the

Head Start program performance standards. Thinkers such as American philosopher John Dewey, Swiss philosopher and psychologist Jean Piaget, and Russian psychologist Lev Vygotsky developed the idea of child-initiated learning. Several research studies support the value of including child-initiated learning in early childhood education. This entry first explains what constitutes child-initiated learning. It then discusses the role of adults in child-initiated learning, what the research on child-initiated learning shows, and organizational support for child-initiated learning.

While child-initiated learning may be simply distinguished from adult-initiated learning, activities may be viewed on a continuum of relative influence by children and adults.

- At the adult-initiated extreme so common with older children, the teacher tells the children to take a textbook out of their desk and open it to a designated page and expects them all to comply immediately. An example with a little more child initiation would be the teacher asking questions with single right answers to which children volunteer the answers; with still more child initiation, the teacher asks open-ended questions to which children volunteer their own answers.

- At the child-initiated extreme, the child obtains raw materials and makes something of his or her own design. At a more teacher-initiated level common in early childhood education, the teacher communicates to children that it is time to select or plan their own activities and they do so. Somewhat more teacher-initiated, the teacher hands out paper and crayons and has children draw what they wish. Still more teacher-initiated, the teacher hands out paper with the outline of a picture, and children color it, staying within the lines to varying extents.

In a 1997 study of the HighScope preschool curriculum, Lawrence Schweinhart and David Weikart suggested distinguishing between high and low degrees of teacher direction of activities and

high and low degrees of child initiation of activities, creating a two-by-two matrix with four cells: High teacher direction and low child initiation characterizes the typical teacher-directed program; low teacher direction and high child initiation results in the traditional nursery school program; low teacher direction and low child initiation leads to custodial care; and high teacher direction and high child initiation, coordinated properly, leads to a developmental interaction program, such as the HighScope curriculum.

Child-initiated learning involves cognitive, social, and physical learning. For example, a child who gives another child three blocks in response to a request is engaging in an activity that has mathematical, social, and physical dimensions. The educational challenge is to maximize the learning that takes place along these and other dimensions. Or, following Vygotsky, the educational challenge is to steer activities toward children's zones of proximal development, the level of difficulty at the upper edge of the child's current level of development.

Another relevant distinction is between inside-out learning and outside-in learning. When children initiate their own learning, they are in an ideal position for inside-out learning, from discovery and thinking about their own experience. They are also open to outside-in learning, from interactions with other children and adults. To optimize outside-in learning in child-initiated learning, the adult must be skilled at engaging in interactive instruction, for example, using new vocabulary words in talking with children, having children ask the adult what the words mean, and then explaining the words to the children.

Child-initiated learning activity is similar to children's play but emphasizes the learning and intentionality of the activity, whereas play is the spontaneous activity of children regardless of its learning or intentionality. Because of these features, it is a better term than *play* to emphasize and delineate the educational value of children's activity. Children's play may include learning and intentionality, but then again it may not, and the openness of the word *play* in this regard can lead

to miscommunication among those concerned about the educational value of children's activity.

How Adults Can Support Child-Initiated Learning

The role of the adult supporting child-initiated learning is quite different from the role of the adult initiating and directing children's learning. When adults initiate and direct children's learning, they expect to be in control of the activity, controlling their own activity and closely directing children's activity, recognizing that children occasionally give wrong answers, misbehave, or fail to pay attention. When adults support child-initiated learning, they do not expect to be in control of the activity. Rather, they share control of the activity with the children; both adults and children influence the activity. The adult follows and is responsive to children's leads, possibly asking questions or making suggestions while doing so. The adult's role shifts from provider of knowledge and center of attention to participant, facilitator of learning, and coach.

From a broader perspective, adults in early childhood programs establish the spatial and temporal context for child-initiated learning. Adults set up the classroom or other learning environment to support such learning. The contrast with teacher-directed instruction should be clear. In the typical teacher-directed classroom, the teacher has a desk in the front of the room, and children sit in rows of desks facing the teacher. Classrooms supporting child-initiated learning have learning centers or activity areas around the room. These areas might be thought of as sub-rooms, in that they are bordered and delineated by the area's equipment. One area might be for drawing and painting materials and equipment; another might be for books and other print materials; a third might be for dress-up clothing and equipment; a fourth might be for large and small blocks; a fifth might be for computers with age-appropriate software. Children initiate their own learning by selecting and going to one of these areas, alone or with others, selecting materials there, and using the materials as they

choose. They can simply choose to do these things, or adults can have a planning time in which children decide, in consultation with an adult, not only what they are going to do but how they are going to do it.

Adults also set up the program's daily routine to support child-initiated learning as well as adult-directed learning. In exclusively teacher-directed classrooms, the daily routine is simply a schedule of teacher-directed sessions—reading, writing, mathematics, science, social studies. In classrooms supporting child-initiated learning, one or more sessions are designated for such learning—play time or work time. Classrooms using the HighScope curriculum, for example, precede this session with child planning time, in which children make plans for activities in small groups led by teachers, and follow the work session with recall or review time, in which children report back to their small group and teacher how their plans worked out and what they achieved. Outside time is also traditionally a time for child-initiated learning. In the context of teacher-directed classrooms, outside time constitutes a recess from teacher-directed activity, and the teacher reverts to a passive, monitoring role. In addition to these sessions, classrooms supporting child-initiated learning have other, somewhat more teacher-directed sessions, such as small-group time, whole-group time, cleanup time, and snack time. These sessions as well can be designed so that children take greater initiative within them, for example, being assigned to obtain and distribute snacks or juice.

Theoretical and Research Evidence for Child-Initiated Learning

The rationale for child-initiated learning may be found in the ideas of Dewey, Piaget, and Vygotsky. In books such as *Experience and Education*, Dewey articulates a way of thinking about education that centers on experiential learning and social interaction. In books such as *The Psychology of the Child*, Piaget sees the development of one's knowledge in the interaction between thinking

and action. In his book *Mind and Society*, Vygotsky articulated his idea of the child's zone of proximal development.

The HighScope Preschool Curriculum Comparison Study provides longitudinal experimental evidence of the advantages of including child-initiated learning in early childhood programs. This study used randomization techniques to assign 68 children living in poverty to three types of preschool programs: one that focused exclusively on teacher-directed instruction, one that provided a traditional nursery school program giving children a lot of freedom to do what they wanted, and one that provided the HighScope developmental interaction curriculum. Although the direct instruction group had an early but temporary edge in academic preparation, the other two groups had several long-term social advantages: They required much less treatment for emotional problems while they were in school and committed fewer felony crimes as young adults.

In 2002, Rebecca Marcon studied the influence of three preschool models on the later school success of low-income children in an urban school district. Six years after their preschool program experience, children who had attended child-initiated preschool classes earned significantly higher grades than children whose preschool experiences had been academically directed.

An earlier study by Deborah Stipek, Rachelle Feiler, Denise Daniels, and Sharon Milburn compared the achievement and motivation of children in child-centered and didactic, highly academic preschools and kindergartens. Those in academic programs had significantly higher reading achievement but lower ratings of their own abilities and expectations for academic success and more dependency on adults.

Endorsements of Child-Initiated Learning

In its position statement on developmentally appropriate practice, the National Association for the Education of Young Children acknowledges and endorses the value of child-initiated learning.

It notes that play is critical to children's cognitive and social development, especially their development of self-regulation, and that children's experiences shape their motivation and approaches to learning, which shape their learning and development. It advocates teachers presenting children with opportunities to make meaningful choices, especially in child-choice activity periods; offering daily and weekly schedules that provide children with extended blocks of time for sustained play, investigation, exploration, and interaction; and providing experiences enabling children to engage in play that stretches their boundaries.

The U.S. federal Head Start performance standards call for a developmentally appropriate approach to child development and education that provides "a balanced daily program of child-initiated and adult-directed activities" (Standards, 2009, para. 1304.21).

CHILD-INITIATED PLAY

Child-initiated play is freely chosen and directed by the child. The impulse for such play is intrinsically motivated and not linked to external rewards. Adults may support children's play, but if they are providing the story line or directing the play, then it is no longer child-initiated. Child-initiated play allows children to pick themes that are meaningful to them and to get to know themselves and the world around them. Such play has been widely linked to the development of creativity, self-regulation, problem solving, and physical and social capacities. It takes many forms, but it can be roughly grouped into three categories: physical, social, and make-believe play.

Child-initiated play grows richer and more complex as children develop. Children need ample time to develop such play, but today's children are often blocked from playing by a number of obstacles, including large amounts of screen time, parental fears, and unsafe neighborhoods. As a result, many children are play-deprived, and there is growing concern that their overall health and well-being are suffering. This entry first discusses the stages of child-initiated play and the types of play in which young children engage. It then discusses the importance of children being able to

take risks in play, the reasons why child-initiated play has not been valued in recent years, and the reasons why it needs to be restored.

Stages of Play

Play begins simply with the infant playing with fingers, toes, and simple objects. A few years later the same child can climb high structures, build complex houses, and balance on logs. Play grows increasingly complex as children's capacities grow. At the same time, their overall development is stimulated by play. Play and child development support each other.

One can see children's physical play develop over time as their physical strength, balance, and coordination develop. Less visible, but of great importance, are the changes in children's make-believe play. The very young child is a realist. When the 1-year-old takes out pots and pans, he or she is engaging in the physicality of the play. The child does not yet have the language or the capacity for make-believe to weave the objects into a story. Two-year-olds begin make-believe play by choosing familiar scenes such as pretend cooking or car play, but they are still strongly linked to reality. Offer a 2-year-old a dish of sand and say, "Here's a birthday cake for you," and the child is likely to eat it. Offer it to a 3-year-old and the child may ask, "It's make-believe, right?" They are just entering the world of make-believe play. The 4-year-old accepts the cake with confidence, decorates it with twigs and flowers, and holds a party. She knows perfectly well that it is make-believe. The 6-year-old goes a step further and can picture her play internally. She can see the cake in her mind's eye and does not need the props. The door to imagination has opened.

Likewise, social play develops over time. In the past, children in the elementary school years were allowed to play freely with their peers and created very elaborate imaginative worlds for themselves. A good example is described in the children's book *Roxaboxen*, by Alice McLerran. It is based on a real experience where a group of neighborhood children played together for years on an unused piece of land near their homes. They built simple houses outlined with stones and other materials and adopted very individualized roles.

Types of Play

A playful, well-balanced child engages in many forms of play that can be divided into three main categories: physical play, social play, and make-believe play. Each has a number of subcategories. In rich play scenarios, all three types of play are present and cross-fertilize each other.

Good play environments provide opportunities for all types of play to occur in ways suited to different ages. Yet most playgrounds today only offer opportunities for large motor play. Open-ended play materials, often called loose parts, can be added to play spaces so that children can change the environment daily to meet their needs. Their play becomes more varied and complex. The integration of loose parts, both natural and manufactured, with built equipment is the approach used in adventure playgrounds in the United Kingdom, Japan, and other countries. Only a few are found in the United States, but there is growing interest in opening more. Adventure playgrounds are rich in child-initiated play and are overseen by playworkers who support children's play without dominating or directing it. A similar approach is taken by schools and parks that store play materials in sheds or pods that can be opened daily by adults. The inclusion of simple, open-ended materials, both natural and manufactured, greatly enlarges children's play experiences.

Physical Play

Children readily engage in large motor activities such as swinging, climbing, and balancing. They use whatever materials are at hand, including built equipment or boulders, hills, and trees. With simple props they dress themselves up and build houses and forts of all kinds. In the process they develop small motor skills with their hands and large motor skills with their whole bodies.

Rough and tumble play is another common form of physical play. It can look aggressive to the unschooled eye, but while engaging in this form of play children do not intend to hurt each other. Their bodies usually remain soft and rounded whereas in aggressive play they become harder and their gestures more pointed.

Children actively use their senses in play and relish having a wide range of materials to explore through sight, sound, touch, smell, and taste. With their hands and sometimes their whole bodies they explore sand, earth, water, and mud. They experience contrasting textures from rough stones to soft silk. They forage for fruits and vegetables growing in gardens and note the many smells of their environment.

In mastery play children repeat the same activity again and again until they have learned it. They may turn somersaults or practice tying bows, but as long as they are choosing the activity and directing it, then it is play. Generally, children will stick with an activity far longer if they've chosen it than if an adult has assigned it to them.

Social Play

Children can play alone but very often they seek out other children and adults to play with. Their earliest social play may be a game of peek-a-boo or a grown-up may tweak their toes to "This little piggy went to market." Such social play is initiated by the adults, but soon young children give their own play cues, rolling a ball to another person or dropping an object to be repeatedly picked up by a willing adult.

Toddlers enjoy playing with others but generally do so through parallel play. They play near one another but usually do not integrate their play with that of another child. When they do interact playfully, there may be a certain amount of grabbing, hitting, and even biting. They rarely inflict any serious harm on one another, and they gradually develop self-control and the use of language to resolve differences.

Three-year-olds begin social play in earnest, albeit a bit clumsily at first and with many small disagreements. By kindergarten most children have become skilled social players and develop fairly complex play scenarios that often begin with the words, "Let's pretend." As the play develops, there is a great deal of social negotiation and rule-making that resolves differences and allows the play to continue over long periods of time.

A generation ago, when elementary-age children had more freedom to play on their own, groups of

children would play together from morning until evening. No one wanted the play to end, so the children were highly motivated to work through any social problems that arose.

Creative Play

Make-believe play calls for a high degree of creativity. Children take whatever object is at hand and transform it into whatever they need. A stick becomes a fishing pole, a sword, a violin bow, or some other object. In make-believe play children take on any role they fancy, from being a parent or child to an astronaut or a doctor, or they can become a wild animal or a pet. Children use role-playing to work through difficult situations in life, to prepare themselves for adult roles, or simply to explore relationships and have fun.

Children integrate all forms of art materials into their creative play: painting, sculpting, making music, developing puppet shows, and much more. They play with language, telling stories, writing plays, making up rhymes and poems, and changing the words to well-known songs and verses.

Taking Risks in Play

There is a difference between hazards and risks in play. Hazards are unexpected problems that children cannot anticipate or risk assess for. Perhaps a piece of equipment is poorly designed or has a broken part. Or there is broken glass hidden in the grass. It is up to adults to inspect the equipment on a regular basis to be sure it is safe. In contrast, risks are visible to children who decide whether and how to climb a tree or leap across a stream.

Risk-taking is an important part of child-initiated play, for children continually set themselves new challenges that stretch their capacities. There is some risk of injury with such play, but children experienced in play are amazingly adept at assessing risk and avoiding serious injury. They know their own abilities and weigh them against the external circumstances. Life is full of risk—from crossing busy streets to facing earthquakes and tsunamis—and it is important that children build

up their risk-assessment skills through play. Probably the greatest risk of all is to grow up not knowing how to assess risk, and this seems to be happening to many children today. Typical play spaces offer as little risk as possible, rather than offering as much risk as children can handle.

No one wants to see a child injured, but it has been long recognized that a certain amount of injury goes hand in hand with being a playful child. The injuries experienced in play can usually be treated with simple first-aid measures, although occasionally a child may break an arm or a leg while playing. Fortunately most children heal quickly. Lady Allen of Hurtwood, who developed many adventure playgrounds in the United Kingdom, is often quoted as saying that it is better for a child to have a broken limb than a broken spirit. To deprive children of play through fear of injury can stifle a child's spirit for adventure, risk, and creative growth.

Disappearance of Play

Fear of injury and lawsuits are among the reasons adults are reluctant to let children play freely today. Other reasons include not wanting children out of sight for fear they will be abused or kidnapped, or because of heavy traffic or a pattern of violence in the neighborhood. Children spend long hours indoors with screens or are enrolled in many adult-directed activities. In the case of preschool and kindergarten children, many programs now resemble the elementary school classrooms of the past with a strong focus on instruction and little time for child-initiated play. Overall, child-initiated play has not been highly valued in recent decades, but numerous articles, films, and books seem to be changing the public attitude. Parents want more play time for their children but are not sure how to accomplish that, given time restrictions and safety concerns.

In addition, teachers, camp directors, and others who support children's play indicate that many children lack play experience and need help to become strong players. They report that many children become active players within a few weeks once they realize it is allowed and even encouraged. Other

children may require intervention by skillful adults in order to play.

Increasingly, there is concern about the ill effects of play deprivation. Children, even in preschool, show serious signs of stress, anxiety, depression, and behavioral disturbances. By certain measures, creativity levels have declined, and social skills also seem to be declining. The loss of child-initiated play is not the only factor, but it is considered to be a major one. Children suffer from a dual problem of being under more stress than they can handle and of being deprived of play, which is their primary way of dealing with stress.

Fortunately, many individuals and a number of organizations and government agencies are taking a fresh look at play and encouraging children to play, particularly outdoors in nature. Among them are the Children and Nature Network, Nature Explore, the International Play Association, the U.S. Play Coalition, Pop-Up Adventure Play, KaBOOM!, and the Alliance for Childhood.

CHILD-PARENT CENTERS

The Child-Parent Center (CPC) education program is a school-based early childhood intervention that provides comprehensive educational and family support services from preschool to third grade to children in predominately economically disadvantaged neighborhoods. The program was designed to improve children's school readiness and achievement and strengthen parent involvement and engagement in learning.

CPC was established as a response to three major problems in Chicago's West Side neighborhoods of North Lawndale and West Garfield Park in the mid-1960s: low rates of school attendance, family disengagement, and low student achievement. Only 8% of sixth graders in area schools were at or above the national average in reading achievement. (For more on this, see *Success in Early Intervention: The Chicago Child-Parent Centers* by Arthur Reynolds, published in 2000.) Based in part on a survey of neighborhood residents, Lorraine Sullivan, schools superintendent for District 8 on Chicago's West Side and CPC founder, believed that the best solution was to design an early childhood program with parents as partners in children's education. The Child-Parent Education Centers opened in May 1967 in four sites serving the most disadvantaged areas of the city. Expansion began soon afterward.

By approving the establishment of CPCs in 1966, the Chicago Public School District was the first in the nation to allocate funds from Title I of the Elementary and Secondary Education Act of 1965 to preschool education. CPC is the second oldest federally funded early childhood program (after Head Start) and the first federally funded comprehensive PreK–3rd program.

Program Elements

As described by Sullivan, the original goal of the program was to “reach the child and parent early, develop language skills and self-confidence, and to demonstrate that these children, if given a chance, can meet successfully all the demands of today's

technological, urban society” (Naisbitt, 1968, p. A; see also Sullivan, 1971). CPC emphasizes five program features: early educational enrichment beginning no later than age 4, parent involvement, a structured language and literacy instructional approach, health and social services, and continuity between preschool and the early grades (Reynolds, 1994; Reynolds, Temple, & Ou, 2003).

The program rationale is that children's school readiness and achievement can be enriched with a whole-child approach to instruction and intensive family support activities in the parent resource room, the school, and the community (Graue, Clements, Reynolds, & Niles, 2004). Under the guidance of the head teacher working in collaboration with the school principal, CPCs provide comprehensive services in the domains of education, health, social support, and family support. As shown in Figure 1, the head teacher directs overall program and instructional supports while the parent resource teacher runs the parent involvement program. The school-community representative conducts home visits and mobilizes resources for families at home and in the community. A school nurse, school psychologist, speech therapists, and clerk have routinely provided support services (Reynolds, 2000; Sullivan, 1971).

Full- or part-day preschool classes for 3- and 4-year-olds are limited to 17 per class with a certified teacher and teaching assistant. Kindergarten to third grade services are provided in classes limited to 25 with teaching assistants in each class. The organizational structure is one of three types: (1) preschool to third grade services co-located in the same school, (2) preschool services in a center in close proximity to the school, and (3) community-based approach in which the preschool is many blocks from the elementary school into which children matriculate.

Effects of CPC Participation

There is strong evidence of positive effects from CPC participation, including short-term gains in school readiness and achievement up to third grade, intermediate-term effects on reading and math achievement and need for school remedial

Figure 1 Child-Parent Centers Program Organization, Element, and Services From Preschool to Third Grade

Source: Reynolds, A. J., Temple, J. A., White, B., Ou, S., & Robertson, D. L. (2011). Age 26 cost-benefit analysis of the Child-Parent Center early education program. *Child Development*, 82(1), 379–404. doi:10.1111/j.1467-8624.2010.01563.x Figure on p. 403. © 2011 The Authors. services, and long-term gains in educational attainment, socioeconomic status, and health. There is also evidence that participation is associated with crime prevention (including reduced delinquency and arrests), increased rates of high school graduation and college attendance, and a variety of indicators of adult well-being (i.e., economic, social, and health behavior). Cost-benefit analyses have also been completed. Because most of the studies use data from the Chicago Longitudinal Study (CLS; Ou & Reynolds, 2006; Reynolds, Temple, Robertson, & Mann, 2001; Reynolds, Temple, White, Ou, & Robertson, 2011), a summary of its background and validity attributes follows.

The CLS is a prospective investigation of 1,539 children who participated in early childhood programs in the Chicago Public Schools in the mid-1980s. The sample included the complete cohort of 989 children who completed preschool and kindergarten in all 20 CPCs in 1983–1986 and 550 low-income children who did not attend the program in preschool but participated in a full-day kindergarten program in five randomly selected schools and in those affiliated with the CPCs. Thus, the comparison group was enrolled in the usual early childhood interventions available for low-income children in the Chicago public school system. School-age services were provided in first to third grades in affiliated schools regardless of children's preschool or kindergarten participation. The comparison group matched the program group on age, eligibility and participation in intervention, and neighborhood and family poverty. Nearly 90% of each group has been successfully followed into adulthood to assess effects on a wide variety of measures of well-being.

The major effects of CPC as reported in previous studies are summarized in the remainder of this section (see Reynolds, 2000). Table 1 summarizes key program impacts for the preschool component in both group differences and effect sizes.

Relative to the comparison group, CPC preschool participants began kindergarten at significantly higher levels of school readiness as assessed by the cognitive composite of the Iowa Tests of

Basic Skills (effect size [ES] = .63 standard deviation [SD]). For example, 47% of the CPC group was at or above the national norm in readiness compared to 25% for the comparison group. Compared to participation for 1 to 3 years, participation in the total program from preschool to third grade was associated with higher reading and math achievement at the end of third grade (ES = .55 SD). Achievement test scores, as measured by the Iowa Tests of Basic Skills, showed a consistent pattern of benefits to age 15 for preschool participants and for children participating in the total program from preschool to third grade (Reynolds & Temple, 1998).

Parent Involvement and Family Support

CPC participants had higher levels of parental involvement in school as rated by classroom teachers and by teachers and parent jointly (Miedel & Reynolds, 1999). Involvement in school was further increased by participation from preschool to third grade (Reynolds, 2000). Preschool participation and extended participation from preschool to third grade also was associated with reductions of 50% or more in substantiated child maltreatment over ages 4 to 17.

Remedial Education

By age 18, the percentage of children receiving special education services or retained in grade was substantially lower in the program group than in the comparison group. For preschool, 14.4% of the CPC group received special education services compared to 24.6% for the no-preschool group. Special education rates for children who were in the program from preschool to second or third grade compared to those who were not were, respectively, 13.5% versus 20.7%. Rates of grade retention were reduced by 30% to 40% or more for all program comparisons (Reynolds et al., 2011).

Delinquency and Crime

CPC preschool participants had a significantly lower rate of juvenile arrest (16.9% vs. 25.1%),

Table 1 Selected Effects of Preschool Participation in the Child-Parent Centers

<i>Domain and Measure</i>	<i>Preschool Group (n = 950)</i>	<i>Comparison Group (n = 523)</i>	<i>Difference</i>	<i>Effect Size</i>
School Achievement/Performance				
Met national norm on cognitive composite—age 5, %	46.7	25.1	21.6*	0.59
Met national norm on reading achievement—age 14, %	35.0	22.0	13.0*	0.38
High school completion by age 21, %	61.9	51.4	10.5*	0.28
Remedial Education				
Grade retention by age 15, %	23.0	38.4	−15.4*	−0.43
Special education by age 18, %	14.4	24.6	−10.2*	−0.41
Child Maltreatment				
Any indicated abuse or neglect from ages 4 to 17, %	9.9	17.4	−7.5*	−0.35
Any out-of-home placement, %	5.2	8.5	−3.3*	−0.25
Juvenile Arrest by Age 18				
Petition to juvenile court, %	16.9	25.1	−8.2*	−0.29
No. of court petitions	0.45	0.78	−0.33*	−0.30
Petition to court for violent charge, %	9.0	15.3	−6.3*	−0.30
Adult Crime by Age 26				
Any felony arrest, %	13.3	17.8	−4.5*	−0.19
No. of felony arrests	0.32	0.44	−0.12*	−0.21
Incarceration or jail, %	20.6	25.6	−5.0*	−0.17
Health and Mental Health				
Reported any depression symptom by age 24, %	12.8	17.4	−4.6*	−0.20
Substance misuse by age 26, %	14.3	18.8	−4.5*	−0.19
Health insurance coverage by age 26, %	76.7	66.6	10.1*	0.30

* $p \leq .05$.

Notes: Effect sizes are in standard deviations. Dichotomous outcomes were converted using the probit transformation. Sample sizes vary by outcome. National norm is for the Iowa Tests of Basic Skills. The sample sizes for adult crime by age 26 are provided. Coefficients are from linear, probit, or negative binomial regression analysis. Coefficients are adjusted for the indicators of preprogram risk status, gender, race/ethnicity, child welfare history, and a dummy-coded variable for missing data on risk status. Sample comparisons are based on published studies whenever possible.

adult felony arrests (16.3% vs. 21.2%), and adult conviction (20.3% vs. 24.7%) by age 24 to 26 in comparison to the comparison group. Few effects on crime prevention were found for extended

CPC participation; the main one was arrests for violence by age 24 to 26 (13.9% vs. 17.9%). No differences for school-age participation alone were detected.

Educational Attainment and Economic Well-Being

Preschool participants had a higher rate of high school completion by age 21 (61.9% vs. 51.4%), completed more years of education by 26 (12.1 vs. 11.8), and had a higher rate of 4-year college attendance (10.9% vs. 7.1%). Corresponding differences were also found in favor of extended intervention from preschool to third grade (Temple, Reynolds, & Miedel, 2000). Relative to the comparison group, preschool participants and participants of the total program also had higher levels of job skills and socioeconomic status by age 28 (Reynolds et al., 2011).

Economic Returns

Two cost–benefit analyses examining the outcomes for participants at age 21 and age 26 show high economic returns from the program (Reynolds, Temple, Robertson, & Mann, 2002; Reynolds et al., 2011). The following summarizes the findings on the program’s long-term effects through age 26 in 2007 dollars.

Preschool. At an average cost of \$8,512 per participant for 1.5 years of service, CPC preschool was associated with an average economic return to society of \$92,220. The largest benefit categories were life-course crime savings that included those to victims, which was 46% of the benefits. Earnings capacity and projected tax revenues contributed 31% of societal benefits. As a ratio of benefits to costs, CPC was associated with a return of \$10.83 per dollar invested in the program. Considering only the public savings to government and taxpayers, the economic return was \$7.20 per dollar invested.

School Age (Grades 1 to 3). At an average cost of \$3,792 per participant above and beyond regular instruction, CPC school-age intervention was associated with an average economic return to society of \$15,064. The societal benefit–cost ratio was \$3.97 per dollar invested. The public benefit–cost ratio was \$2.11.

Preschool Plus School Age (Extended Intervention). Compared to children with 1 to 3 years of CPC intervention, children in extended intervention for 4 to 6 years had an average economic return of \$42,520. With an average cost of \$5,163 per participant, the benefit–cost ratio was \$8.24. The public cost–benefit ratio was \$5.21.

Mechanisms of Effects

The paths through which CPC preschool participation affects later well-being have been investigated in many studies. Five processes have been identified to explain these benefits and are referred to as the five hypothesis model of intervention effects (SHM). The hypotheses are cognitive advantage, family support behavior, motivational advantage, social adjustment, and school support. Arthur Reynolds, Suh-Ruu Ou, and James Topitzes (2004) investigated mechanisms to high school completion and juvenile arrest. They found that cognitive advantage, family support behavior, and school support were the strongest mechanisms of influence. Cognitive advantage paths, as measured by school readiness skills, accounted for 23% and 19% of the indirect effects on school completion and juvenile arrest, respectively. Corresponding percentages for family support were 28% and 21%, and for school support were 31% and 48%, respectively.

CPC Scale Up

Although CPC has a distinguished history of benefits to children and families, expansion of the program to other settings is a major priority. In 2012, the U.S. Department of Education awarded the University of Minnesota an Investing in Innovation grant to expand the CPC program from 10 to 26 schools as a school reform model. Implemented in five Illinois and Minnesota districts, the Midwest CPC Expansion began in the fall of 2012 for a preschool cohort that will receive intensive educational and family services through third grade (2012–2017). More than 10,000 children will receive CPC program services with a major goal of sustainability within the districts. A matched comparison group similar to that in the CLS will help gauge effectiveness.

Participation in CPC PreK–3rd is expected to promote enduring positive impacts for three major reasons: (1) A longer duration of participation will produce greater and more foundational changes in school achievement and performance; (2) the program encourages stability and predictability in learning environments; and (3) it is implemented during the transition to school, a critical phase of development in which continuing services can accelerate learning and lessen the possibility of drop-off effects. The results of many routinely implemented programs show that they are insufficient by themselves to substantially reduce the achievement gap. Effective preK has been found to reduce this gap by about a third by the end of Grade 3. This expansion is consistent with the reform goal of scaling up the most effective PreK–3rd models.

Conclusion

There is strong evidence on the positive and enduring effects of high-quality early childhood programs. There is not only a critical mass of evidence from long-term cost–benefit analyses of CPC and other preschool programs but also increasingly strong evidence from state-financed preschool that participation is associated with sizable increases in school readiness and early achievement. Moreover, advances in knowledge on the mechanisms of long-term effects have strengthened confidence in the economic returns of programs. The findings from the CPC program provide a strong foundation for improving children’s well-being. Expansion of the CPC PreK–3rd model provides an opportunity to increase and further sustain the documented effects for more children and families.

CHILDREN'S CUBBIES

Children's cubbies mostly refer to the bins or spaces that house children's belongings that are transported between the home and classroom. Cubbies typically house and store children's items such as shoes, hats, coats, gloves, materials (from home, too), work to go home, saved items, pillows and blankets, backpacks, and sometimes found treasures. Cubbies can offer a way for children and families to have their own storage space in the classroom or school, and often they represent a space between home and school. Occasionally a single cubby is shared between children. However, this practice of sharing a single cubby for multiple children is more and more discouraged in regulations and guidelines because of contagions and communicable outbreaks. As well, certain items from home such as over-the-counter and prescription pharmaceuticals (sunscreen, medications, etc.) may be regulated and need an alternatively secured and marked cubby location.

Cubbies are found in the early childhood classroom in various settings and are recommended to be located nearest the entry area to help transition children to and from classroom spaces at the beginning and end of their time each day and throughout

the week. The cubby space can represent an entry zone into the classroom; this way, as children and families enter and exit a space, they can ready themselves for the transition in and out of the environment.

Many cubbies are made from durable materials such as protected or painted hardwood or durable heavy plastics or metals in case of nearby spills or impacts. Cubbies are typically labeled with the child's name and/or symbol to reference the child's name, which gives them a place to call their own in a shared community. If described and explained, cubby spaces can offer a relevant experience to the school's culture as an interface to each family's way of living; where materials from home can be kept safe, a family respectively uses their own space and the overall community engages in a shared understanding of the uses of cubbies in the school.

In many instances, the school personnel rely on the cubby space as a means for program-to-family communications. Generally, papers and materials to go home or a note from the teacher can be found in or near the child's cubby. Signing in and out for the day often occurs near cubbies, and possible daily snapshots or interest fliers are posted nearby. Cubbies are a typical focal point of the important shared resources between home and school, especially around child necessities such as diaper-packs and baby wipe containers for younger children and other classroom materials such as specialty pencils, paper, or a book from home for older children.

Play and work on and near the cubby storage vary from program to program. Because cubbies host personal items, it is common for children to go to and linger near their cubby space to remind themselves of home and family. The relationship between the child and their cubby space may become strong as a result of the links and connections to home, which for some children offer safety, security, and another world. Cubbies may provide a space for small groups to assemble, explore an item stored there, and create fantasy play in or near the space; in this way, cubbies can offer social confidence and closeness or a place to recharge one's own energy in solitude. Thus,

storage reaches beyond physical resources and into memory and fantasy play in spaces. Cubbies can offer alternative worlds and spaces linking school experiences to home and back again.

Often, the cubby space is not licensed or regulated as an ongoing learning space for the classroom if it is separated off from the main floor plan. If the cubbies are open to the classroom, the aesthetics of the materials contained within should be considered. Coat hooks, boot bins, and other carry crates may be necessary to keep supplies, materials, and storage items out of walkways. Also, how much access children have to all cubby spaces can be well thought out. For example, lower tubs can be used for shoes and home-to-classroom materials, coats can be hung in a middle zone, and an upper bin can be brought down for more particular occasions or by request of the child. Providing easy access to a child's own cubby provisions creates a sense of autonomy as well as responsibility for their maintenance, upkeep, and care.

Upholding aesthetic considerations for storage spaces is essential; for example, a visible overflow of too many storage items could mean additional space is required. For example, bulky items like diaper-packs, plush-toys and blankets, balls, or big books from home may need a secondary storage space for each child. Secondary storage spaces can be labeled and placed in suitable locations such as diaper-packs near infant and toddler changing stations, extra clothing in bathroom storage bins, and books in individually marked totes near a reading corner.

Another important aesthetic to cubby spaces includes featuring lids and doors as a way to keep items from falling out into walking zones or to maintain an appearance of order and tidiness in the overall environment. Further, cubbies require routine maintenance, clearing, and sanitizing as well as general daily attention by the whole community.

Overall, in early childhood settings, shared spaces and cubbies create occasions for considering everyday life. Cubbies offer opportunities for young children to learn about concepts such as organization, keeping their materials uncluttered

and in good condition (e.g., keeping marking pen caps on pens when stored so the pen does not stain other storage items), and trust in others to respect personal items in open and shared spaces. Cubby spaces also help young children learn about storing resources carefully, having a respect for others' space, and caring for the environment and supplies around them. Designing spaces such as cubbies that connect the home and early learning settings for children and their families honors the individual and the school community as a place of learning and living.

CHILDREN'S LITERATURE

Children's literature is the subset of literature designed for and loved by children. For the purposes of this entry, children's literature will be used to refer to literature for early childhood: an audience of children from birth to third grade and the adults who care for them. Children's literature includes picture books and picture storybooks; board books and wordless books; alphabet, counting, and other concept books (e.g., opposites, colors, animal sounds); nonfiction and information books; folk and fairy tales; movable, pop-up, and toy books; and poetry and song books. Children's literature is crucial to young children's development

from their early oral language encouraged by nursery rhymes and songs; to their pre-reading skills as they are read to and play with books; to their eventual independent reading skills.

It is a rare child who becomes a good reader without exposure to children's literature in his or her preschool years. It is perhaps rarer still to find an adult who loves to read who did not develop a love of children's books before he or she attended school for the first time. This entry presents a brief history of children's books; the differences among trade books, textbooks, and mass-market children's books; how children's literature promotes learning to read; the importance of libraries; and the availability of a wide range of children's literature.

History

The first picture book for children was written by a Moravian bishop and educator, John Amos Comenius. Published in 1657, *Orbis Pictus* (*The World Illustrated*) was more of a one-volume encyclopedia than what is considered a picture book today, but it was designed to be interesting to children and it achieved that purpose. Children's books have gone through many phases in the 350 years since *Orbis Pictus* was published. Many of the early works were quite didactic, designed to inform and educate, especially in the ways of religion and proper behavior. However, children often found things to like in spite of the lessons inherent in that literature. They learned to skip the boring parts and focus on the interesting characters and most especially, a story well told. They would also find the occasional book that was written for a very different audience and make it their own. That is how Daniel Defoe's *The Life and Strange Surprising Adventures of Robinson Crusoe* (1719) and Jonathan Swift's *Gulliver's Travels* (1726) became favorites that are still in print three centuries later. Although not especially suitable for very young children, these two books marked the start of children expressing an interest in books, despite the books not being specifically published for them. Children became their own advocates for children's books.

By the mid-19th century children could choose from among many selections, including the Grimm brothers folktales translated from the original German, the nonsense rhymes of Edward Lear, the fairy tales of Hans Christian Andersen (1846), Lewis Carroll's *Alice's Adventures in Wonderland* (1865), Mary Mapes Dodge's *Hans Brinker, or the Silver Skates* (1865), and Louisa May Alcott's *Little Women* (1868–1869). At the end of the century the picture book was gaining strength through the works of three talented British illustrators—Kate Greenaway, Randolph Caldecott, and Beatrix Potter. All three were creating images that had children in mind as the primary audience but that also appealed to the adults who were buying them for their children.

Publishing children's books in the United States received an important boost when Macmillan created the first U.S. children's book imprint in 1919—Macmillan Children's Books. Within 10 years there were nine children's publishing houses in the United States and the number of new books published for children had more than doubled to 931 per year by 1929. *The Horn Book Magazine*, which was entirely devoted to reviewing and promoting children's literature, was founded in 1924. The next three decades were often referred to as the golden age of children's books in the United States. It is when the English-language children's literature's "headquarters" shifted from England to the United States, many publishers increased their attention to picture books, and scores of new writers and illustrators entered the field.

Many of the new creators were recent immigrants, and the books published in the United States reflected a broad mix of adventures, cultures, and optimism. In 1938, publisher Frederic G. Melcher, who had founded the John Newbery Medal for the most distinguished contribution to American literature for children in 1921, offered the American Library Association a comparable annual award for "the artist of the most distinguished American Picture Book for Children published in the United States during the preceding year." The Randolph Caldecott Medal was first given to Dorothy P. Lathrop for *Animals of the*

Bible in 1938 and has been awarded to an illustrator every year since then.

The world of children's books is broad and multipurposed, but the books that are most compelling to children are generally those that do not attempt to teach them or push strongly in a particular direction but rather are intended to inform, comfort, and inspire them.

Trade Books Versus Mass-Market Books Versus Textbooks

Although a book is a book—a nonperiodical hardcover volume regardless of length—there are distinct general categories of children's books based on their potential markets. Children's literature most often refers to children's books designed for the general consumer and sold primarily through bookstores and to libraries and schools—known as trade markets. Although trade books were traditionally hardcover, in the last half century, softcover and paperback trade books have become much more common.

Mass-market books are sold predominantly through venues that extend beyond traditional trade outlets such as bookstores, to include drugstores, chain stores (e.g., Walmart), and supermarkets. Mass-market paperbacks are usually printed on less expensive paper than trade paperbacks.

Textbooks are designed for educational or classroom use rather than general use. Textbooks also include workbooks, manuals, and other items intended for the classroom. They often contain teaching aids, such as summaries, questions, and practice tests or quizzes, that distinguish them from trade and mass-market books.

How Children's Literature Promotes Learning to Read

Literacy

Literacy in its broadest sense includes reading, writing, listening, and speaking. And, it involves more than those four skills in isolation. A truly literate person engages in those behaviors within a social and cultural context and is disposed toward

a lifelong use of those skills that help improve the enjoyment of one's life, in all of its stages. The earliest literacy skills begin with infancy and the use of songs and rhymes to soothe and entertain babies. Although they were once part of an oral tradition, songs and rhymes that soothe and entertain today come from children's books.

It comes as no surprise that there is a close relationship between good children's literature and effective learning experiences for young children. The relationship between them is made possible by a caring adult—the parent, caregiver, educator, or librarian who knows about children *and* children's literature. This adult knows how to keep a toddler listening to a poem, how to select a story that will please 95% of all 3-year-olds, how to ask questions to help a 5-year-old understand a challenging story, and how to find an information book that readily satisfies a 7-year-old child's current passion.

Reading Aloud—Bringing Children to Books

One of the most powerful uses of children's books in early childhood is reading books aloud. There are books for every child, at every age. Many of the research findings regarding children's books in early childhood education focus on access to books and reading aloud. These findings include the following:

- Children's early experiences with children's books are among the most significant correlates with their success in learning to read in school.
- Children are more motivated to request being read to, and to "read" or explore on their own, from books with which they are already familiar or have heard or read before and have enjoyed.
- There is a positive relationship between how much children have been read to and how well they will read.
- Storybook reading is a more effective influence on literacy development when children have opportunities to engage in conversation about the story.

The Children's Book Committee of the Bank Street College of Education has compiled a helpful

list of *Tips for Parents* regarding children's books that is based on research and grows from its decades of experience working with young children and their caregivers. Tips include talking about reading with children and continuing to read aloud to children even when they are able to read independently.

Reading children's books aloud to children is such a powerful tool that many children are able to learn to read without any further instruction. Even those children who require more assistance with reading are more motivated by their love of children's books to learn to read.

The Place of Children's Literature in Early Childhood Programs

Personal Reading Versus Reading to Learn

Children's literature has been incorporated into many educational curricula in all grades, as a result of studies showing that it enhances children's reading skills, vocabulary comprehension, and much more. Furthermore, the abundance of varied and high-quality children's books is often effectively used to support children's learning across the curriculum in areas such as mathematics, science, and history, as well as their traditional partner reading. Amid these excellent uses of children's literature, however, we must remember the importance of children's literature for singular and personal reasons. Children's books nurture the curiosity of the first grader who is fascinated by birds, they support the budding artist in love with color, and they provide a home for the imagination.

Windows Versus Mirrors

Children's books provide windows to the world, real or imagined. They give children a chance to go anywhere and do anything. Sometimes those windows offer an alternative view to a hard life—they offer a child hope. A good collection of children's books should also offer children mirrors. Every young child should be able to see himself or herself in books—not every book, certainly, but in some. That

combination of windows and mirrors makes children's literature a powerful source for learning about others and for affirming the importance of self.

Beginning in the 1960s children's book characters began resembling the real world. In 1969 the Coretta Scott King Book Awards were founded to honor African American authors and illustrators of books for children that demonstrate an appreciation of African American culture and universal human values. In 1996 the Pura Belpré awards were founded to honor Pura Belpré, the first Latina librarian at the New York Public Library. They are presented annually to a Latino/Latina writer and illustrator whose work best portrays, affirms, and celebrates the Latino cultural experience in an outstanding work of literature for children and youth.

Classroom, School, and Public Libraries

Types of Children's Literature

The broader the variety of children's books available, the more likely it is that there will be books to appeal to every child's individual interest. Some books are perfect for group activities and others for sharing while sitting on an adult's lap. Some books are best shared or explored at home. It sometimes pays to purchase more than one copy of a book that is a big hit because of a storytime theme or particular time of the year. Every library should have a broad sampling of poetry, songbooks, and nursery rhymes; board and cloth books; concept books; and wordless picture books. Even when a classroom library is serving children age 3 and older, it is important to remember that the whole family is also being served—the parents, grandparents, and new siblings as well as the 3-year-old in the classroom. Sampling all the languages spoken in the school or community is also a wise approach to collection development.

Folktales and fairy tales are a critical component of any early childhood library. Fairy tales are stories that include supernatural characters such as fairies, witches, ogres, trolls, or giants who often have the power to predict the future, control the present, or take on different shapes. Fairy tales can

be folk fairy tales, stories passed down through the oral tradition where the original author is forgotten, or literary fairy tales written by a known author. Hans Christian Andersen is one of the more famous literary fairy tale creators. A folktale is any timeless story that comes down through the oral tradition. Every culture has them, and it is delightful to compare versions; for example, many trickster tales tell the story of the little creature using his quick wits to tease or best the bigger creature. The teasing is often met with comeuppance for the trickster, while the besting of the bully might be celebrated. Trickster tales sometimes feature Anansi (from Africa), Brer Rabbit (from the American South), or Coyote (from Native American tribes).

Picture books and picture storybooks are the mainstay of any library serving young children. Two special categories of picture storybooks are especially useful and popular in early childhood settings—predictable stories and cumulative tales. Predictable stories are designed for children to figure out what comes next. Sometimes a rhyming word pattern provides the clue, while other times certain words or phrases are repeated. Predictable books allow children to prepare for independent reading through imitation or “pretend” reading. Their pride in reading the book is easily seen and felt. Cumulative tales are narratives that have a simple chain-like plot developed through a pattern of repetition in which phrases, objects, or actions are added one at a time until the complications are resolved. “I Know an Old Lady Who Swallowed a Fly” is a classic cumulative tale in the form of a song where the old lady swallows one animal after another to catch the last one she swallowed.

A relatively new format of picture book is gaining popularity these days—the graphic novel, a chapter book length comic book designed for younger readers. The minimal text and reliance on comic-like art makes them a huge hit with children who prefer less text and stories told primarily in pictures. Easy readers or beginning readers are picture books or picture storybooks with a controlled vocabulary designed for beginning readers. Dr. Seuss is credited with creating the first beginning reader, *The Cat in the Hat*, in 1957.

Information books provide factual information about anything in any format. Some children have no interest in stories or make-believe; they just want the facts and, fortunately, there is a genre right up their alley!

Toy books or pop-up books or movable books are children's books in which parts of the pages pop up, pull out, or extend by lifting a flap. Toy books are designed to invite interaction with the text and are sometimes as much toys as they are books. Most often used by children who want to touch and manipulate things, toy books typically have a much shorter life span than standard picture storybooks. A willingness to replace these types of books gives all children a chance to experience them over time. Books on tape, CDs, DVDs, and computer and tablet applications have become a huge supplemental industry to book publishing. Although it is never a great idea to replace books altogether, recorded books, filmed books, and book-based applications provide expanded experiences—a chance to travel with children's literature-based content or to fill in a space where a book may be less suitable—in a doctor's office, in the back seat of a car, or on a family film night.

The Children's Literature Continuum

Some books that young children treasure occasionally test the patience of adult readers when they are asked to reread them over and over and over. It is still a great idea to reread anything a child wants to hear multiple times, but it is not always easy. On the other hand, there are books that some adults think a child *should* like—occasionally purchased by out-of-town grandparents—that just don't interest the child at all.

Think of those books the children love to the exclusion of parents on the far left of a seesaw and the books loved by parents to the exclusion of the kids on the far right. Ideally, children and their adults should be exposed to as many books in the middle as possible—the books that both children and parents love in equal measure but not always for the same reasons. Those shared children's book experiences can be the most powerful and lasting. Sometimes particular phrases, expressions, and

Figure 1 Children's Literature Continuum

Source: J. Harlan Ritchey.

stories from those books in the middle become part of the family's shared language for generations.

Children's Literature Sources

People Who Know Children's Literature

The best three sources for finding children's books suitable for particular children are the local public library, the school library, and the local bookstore. People who work with children's literature every day are asked over and over again about suitable books for girls versus boys; good books for particular ages; books that might be of interest to reluctant readers; a good next book for a child who just loves a particular author, illustrator, series, or genre; and scores of additional questions. Communities that still have an independent bookstore or a trained librarian in the public school classroom are especially fortunate.

The people working in the children's section of the public library are often trained in the field of children's literature and hold an advanced degree in library science. They are also very likely to love their work—the vast majority of people working with children's books do so because they are passionate about the field. Public libraries also have access to best book lists, lists of book awards,

and bibliographies that can serve as guides for parents, caregivers, teachers, and, sometimes, children themselves.

Organizations That Promote Children's Literature

The American Library Association (ALA) is a nonprofit organization based in the United States that promotes libraries and library education. Founded in 1876 by, among others, Melvil Dewey, inventor of the Dewey Decimal Classification system, ALA is the oldest and largest library association in the world. It also has divisions that focus on school libraries (American Association of School Librarians [AASL]) and children (Association for Library Service to Children [ALSC]). The ALSC is especially well known for its book awards, including the Robert F. Sibert Informational Book Medal, the (Theodor Seuss) Geisel Award for the most distinguished beginning reader of the year, the Randolph Caldecott Medal for the most distinguished American picture book for children, and the John Newbery Medal for the most distinguished contribution to American literature for children.

The International Literacy Association (ILA) is a global advocacy and membership organization of more than 300,000 literacy educators, researchers, and experts across 75 countries. For most of its 60-year history, the ILA has been known as the International Reading Association (IRA), setting the standard for how literacy is defined, taught, and evaluated. Its mission is to empower educators, inspire students, and encourage leaders with the resources they need to make literacy accessible for all. Some of its many resources include publications focused on early childhood education and recommended children's book lists.

The Pennsylvania Center for the Book (PACFTB) is a state affiliate of the Center for the Book at the Library of Congress and sponsored by Penn State University Libraries. Every state has a Center for the Book, and each approaches celebrating the world of the book and literacy in its own unique way. Pennsylvania's primary focus is on young children and children's literature. In addition to a family literacy curriculum used in family literacy programs

across the country, the PACFTB issues an annual best book list for children ages 3 to 6—*A Baker's Dozen: The Best Children's Books for Family Literacy* published in the preceding year.

Publications That Provide Annual Lists of the Best Children's Books

A Baker's Dozen: The Best Children's Books for Family Literacy is a best books list of 13 picture books especially suitable for family literacy selected by PACFTB with parents who are not strong readers in mind. Tips for using the books with children and with families accompany the list.

Best Books of the Year for Children and Young Adults is a best books list selected by the Children's Book Committee of the Bank Street College of Education in Manhattan, New York (founded in 1916). The two youngest categories on the list are *Under Five* and *Five to Nine*—both of which contain well over a hundred annotated titles each year.

The Bulletin of the Center for Children's Books is a children's literature review journal published monthly except August (University of Illinois/Johns Hopkins University Press). In addition to monthly reviews and a simple recommendation code (marginal, acceptable, recommended, special distinction), the bulletin staff select the best of the previous year's literature for youth and award a Blue Ribbon to each selected title. The list is published and released online every January, citing the previous year's books.

Children's Choices is an annual joint project of the ILA and the Children's Book Council (CBC). The CBC is the nonprofit trade association of children's book publishers in North America, dedicated to supporting the industry and promoting children's books and reading. Each year, approximately 12,500 children (Grades K–6) from different regions of the United States read and choose 100 favorites from books donated by North American children's book publishers. About a third of the list is made up of books for beginning readers, Grades K–2, ages 5 through 8.

The Horn Book Magazine is the oldest children's literature review journal in the United States, founded in 1924. Every January in the first issue of

the new calendar year, *Horn Book* publishes its Fanfare—the succinct list of the two or three dozen best children's books of the preceding year.

Notable Children's Books is an annual list of outstanding children's books selected by a committee of the ALSC. As applied to children's books, the list is thought to include books of especially commendable quality, books that exhibit venturesome creativity, and books of fiction, information, poetry, and pictures for all age levels (birth through age 14) that reflect and encourage children's interests in exemplary ways. The current year's Newbery, Caldecott, Sibert, and Geisel Award and Honor books are automatically added to the list. The "Younger Readers" section covers preschool to Grade 2 (age 7), including easy-to-read books, and comprises nearly half of the annual list of approximately 100 titles.

CHILDREN'S WRITING

Imagine writing time in a kindergarten classroom in an urban area in the United States. It *is* writing time, but the children's compositions are being woven through many symbolic media. Children are not only nor even mainly writing; they are drawing, gesturing, conversing, pretending, and, on occasion, singing. This is what writing time may sound and look like in an early childhood classroom that

makes time and space for children to be writers.

This entry first discusses the foundational importance of children's weaving of symbols to their development as writers. As Lev Vygotsky explained, young children's use of the written symbol system builds on their social play with other symbolic tools. Against this backdrop of young children as symbol users and social players, the entry then discusses children's socialization into written language use, their grappling with the encoding system, and their appropriation of writing for use in the cultural worlds of childhoods. The emphasis is on how these processes are enacted in classrooms, since it is in classrooms that, globally, most children experience formal expectations for their writing.

For purpose of this entry, *writing* is defined as the intentional use of particular graphic symbols—letters or letter-like shapes—to represent and communicate meaning and, thereby, participate in situated, culturally valued activities or practices. Young children explore the medium of written language as they do any symbolic medium. But they do not want to learn to write in order to master isolated skills or to contribute to the future economic well-being of their country. They want to participate in the activities going on around them. For children to participate meaningfully in their worlds through writing, that writing must be relevant to them as children.

Composing is a broader term and involves the intentional use of any, or a range of, symbol(s). Given the increasing importance of Web-based, multimodal texts, the goal of writing development has been reconceptualized by many educational scholars. Rather than the mastery of one symbolic medium (i.e., a mastery of a hierarchy of written language skills), the goal is children's intentional design of a multimodal text; such a goal implies a rich symbolic repertoire.

Children as Symbol Makers: Writing and Children's Symbolic Repertoire

Children's writing is often portrayed along a linear line emphasizing encoding: from scribbles and mock writing to invented spellings that map

sounds onto written letters, leading ultimately to texts that are not only readable but also increasingly long and complex. One problem with this linear line is that it hides from view the central role of children's symbolic repertoire; within that repertoire, children find a niche for written language.

In the early childhood period, children develop as symbol users and social players, and, as noted, that development is foundational to learning to write. To illustrate this developmental importance, imagine two preschoolers playing with a large box lying so that its open top is now on its side, facing the children. "This is our house," says one child to the other.

"It's raining, it's pouring," sings the other. The two children crawl in the box and peek out their "door" at the rain.

The children in the scene just described are composing a world. With their talk and actions, they make a box a house and themselves housemates. In their world, they are safe from the storm. Consider again now the "door" of the "house." Since the box is a house, the open side is a door. This is second-order symbolism—one symbol (the box as house) serves as the basis for a second (the open side as door). It develops first in play, but it is also the basis for written language, in which one symbol (a graphic word) symbolizes another (a spoken word).

During the preschool period, when children's coordinated nonverbal play gives way to more elaborate use of language, children's talk may be used to establish the play frame, to name the transformed identities of people, objects, and places (e.g., "This is our house"), and to carry the narrative forward. If one listens to preschoolers drawing, one may well hear very similar kinds of playful talk. Energized by the intention to represent and, often, to play with peers on paper, drawing can become a mediator of dramatic play. "This is my house," a child might say as she makes a box on a page. "Here's you," the child may continue to a peer. In their 2009 book, Celia Genishi and Anne Haas Dyson describe two children playing this way, with kindergartner Willo announcing, "We're playing sisters, on paper," after her friend Alicia put her in a drawing of her family. Thus, through

talk and action, drawing can become a means for articulating a world.

Within this semiotic theater of drawing, children in literacy-infused environments sometimes begin to write letters or words, especially their names. Their actions are often fluid, exploring visual and letter symbolism as their meanings evolve. Among preschoolers and kindergartners, a letter *p* might be reimagined as a person whose hair is on one side of her head; the first letter of a name might be placed in a house, indicating the person who lives there; the letters of sports teams might show up on a drawn football field, along with the associated visual symbol. Eventually, thought Vygotsky, children must learn that they can draw speech—voices, as it were, not just objects.

Vygotsky imagined a linear line from playful gesture to drawn line to written language, all means for articulating ideas. Yet children do not move linearly from one mode of representation to the next. Rather, children may compose worlds through symbol weaving, as written language finds a place in a child's symbolic repertoire.

Entering into writing practice entails imagining oneself as having some agency, some resources, and some companions with whom to venture forward. When written texts are conceived of as yet another place for play, children may experience the transformation of meaning across media, as themes and play practices travel across—and rework—borders of time, space, and media. The role of social and symbolic play in learning to write may not be recognized when formal schooling begins in kindergarten.

Socialization of Young Children as Writers

From a sociocultural point of view, children learn about language, oral or written, as a symbolic code at the same time that they learn how it is used in their social worlds. Familiar writing practices may include contributing to list making for needed items, seeking parent signatures on teacher permission forms, signing one's own name on greeting cards, being aware of texting and even by pretending to

text on cell phones, and on and on. Children's understandings of written language—its function, use, and interactive processes—are energized by the desire to participate in, or play with, such practices, which may vary greatly in nature and extent. This variation exists because language is infused with social and cultural meanings whatever its mode (oral, written, some multimodal or multilingual combination). Because children must build with what they know, and because there is such variation in what children know, there is no set order, no set pathway, to writing.

Writing processes and their functional nature become accessible as they are enacted in talk-filled social activities or events. It is talk that makes the silent marks on page or screen speak for young children. Children learn that certain kinds of texts quite literally have a typical voice or sound. Consider the melodious sound emanating from the church hymnal, the melodramatic dialogue of the superhero cartoon, the celebratory voice of the “happy birthday” greeting card, the straightforward voice of the grocery list, the sweetly affectionate voice of the “I love you” note, and the stern warning of the “DO NOT ENTER” sign.

It is no surprise, then, that young children may write messages before they control the conventional symbol system. They may, in effect, draw what writing looks like, capturing its perceptual features. Writing has a certain linearity, a particular directionality, and specific kinds of letter and punctuation units; the nature and arrangement of those units vary, depending on the spatial location of print. A written bit of correspondence, a sign on a building, a Web page on a cell phone—all may look different. Having made writing, children may assume others can read their text, as in the title of Marie Clay's generative book on young children's graphic explorations of writing *What Did I Write?*, or they may read the text themselves, remembering the intention they brought to their work and adopting an appropriate voice. Five-year-old Alicia wrote letters and letter-like forms in linear rows quickly and then read sweet, loving texts about how “nice and pretty” her two best friends were . . . unless she was mad at them.

With interactive assistance from teachers and peers, children will grapple with the complex encoding system.

Grappling With Encoding

Children's first efforts to choose specific letters to represent particular entities tend to involve names. Alicia's first written words were her own name and that of her best friend Willo. This writing of names, though, does not mean that children grasp the encoding system. In the written system, symbols do not directly link to referential meaning. Rather its units—its arrangements of letters and spaces—are linked in a systematic way to spoken language. Written letters, then, may initially be drawn and directly represent or belong to a referent; an “A” belonged to Alicia. Children may even choose to write a number of letters based on the size of the referent (e.g., large objects may get many letters); more conventionally, they may base decisions on the number of syllables they hear in a word or the sound qualities of letter names (“car” has an R). With experience writing (and classroom talk about letters and sounds), children may invent more phonologically complete representations of spoken words.

However, the same child can use a range of encoding strategies, depending on that child's purpose, the complexity of the intended message, and the ongoing situation, including any interactive guidance. Teachers can hear when children begin to grasp both the notion of one spoken word matching one written one and that of the phonological helpfulness of a slowly spoken word. Children's writing processes will slow down, and, along with social talk, they will use self-monitoring talk as they recite a planned word, try to recall its spelling, find it displayed in the classroom, or pronounce it slowly, before making decisions about which and how many letters to write; then they may reread what they have written before moving on to the next planned word. Writing even a single sentence can initially take much effort. It is worth that effort, though, if children are primed for participation. And this may be especially so when writing becomes part of childhood cultures.

Classroom Writing: Official and Unofficial

The intention to join in, to participate in a communicative practice, compels young children to orchestrate their knowledge and know-how about writing (and other modes), to become aware of a need for help, and to seek out an audience if one is not provided (e.g., through a daily sharing time). Indeed, the enactment of any symbolic act involves grappling with the connection between symbolic vehicle (e.g., the graphic), intended meaning, and the relationship between self and addressees.

From a global perspective, most children's writing education emphasizes isolated skills, beginning with opportunities, not to explore the system but to master the letters and their sounds though such activities as reciting chants (e.g., "A, Apple; B, Boy; C Cat," and so on), copying words from the board, and completing varied paper or computer-mediated practice tasks or "games." Even if a child attends a preschool centered on exploration and dramatic play, as that child goes through a school system, writing tasks are likely to become more constrained and less open to children's resources (e.g., their drawing on popular culture texts, using devalued languages, even talking with peers).

In the United States, teachers in schools serving mainly minority children may have relatively more restrictive curricula and, indeed, in kindergartens, have had such restrictions for a longer period of time than schools serving students from a higher socioeconomic status. Even in classrooms with curricula that encourage daily child composing, the adopted commercial programs may strictly regulate throughout a district what genres children will write, how and when children will proceed to write, and what skills should be mastered by what date. There may be firm expectations for standard grammar, although linguistic diversity in English variants or in home languages is the norm in urban schools in this country, and similar situations prevail globally. Similarly, standard punctuation conventions may be expected, although the syntactic basis for punctuation is rarely clear to young children. (Children's initial use of punctuation tends to be based on spatial cues, like putting periods at the end of lines.)

However, no matter how constrained the official curriculum might be, composing may become important in unofficial or peer-defined cultures. Given children's desire to participate and gain companionship, they may act as agents in writing spaces shared with other children. Such actions require some time and space for talk among peers. If present, writing may become a kind of textual playground. That playground may be found in children's reinterpretations of official school writing practices or in child-initiated activity in unstructured breaks in the school day.

Young children have been observed to enact varied kinds of child-initiated play in official writing times. For example, in an urban first grade observed in Dyson's 2013 ethnography, *ReWRITING the Basics: Literacy Learning in Children's Culture*, children's writing games included pretend birthday parties. Child writers imagined the birthday parties they were having and named peers who were coming, and those peers responded with pictures and texts about the good time they would have at the parties. Even seemingly straightforward texts, like Tionna's—

On Monday I wint.

to the stor with.

Jeanette lyron to

—were play. Tionna's text was part of friends' coordinated play, as similar texts were written on their separate papers. Tionna and Lyron did not even know where each other lived, but writing was a way to mark and sustain relationships that mattered. Indeed, many young children write texts featuring their friends.

Toward Children as Writers

Solely as fragmented skills, writing tasks do not grip children's attention. Further, classrooms that devalue play and silence children can be difficult places for writing to flourish, that is, for children to use their social relations and symbolic repertoire to make writing a relevant tool for them as children.

Yet, all children bring their symbol-producing predilection to school—their talking, drawing, playing, storytelling, and, in our society, some kind of experience with print. The ability to share symbols and thereby organize and express inner feelings and experiences is a part of children's human heritage. Moreover, time to play out their own dramas, to draw real and imagined worlds, to contribute to written accounts of their observations in study units, to hear stories and to compose their own across multiple media and technologies—these are means for helping young children recognize written language as a relevant tool in their lives.

Official tasks that allow children to participate in different ways with different resources may allow teachers to observe what children attend to and, so informed, to extend individual knowledge and know-how. Among such tasks are drawing pictures, dictating stories, and engaging in varied kinds of official and unofficial writing activities. If interactive space and time for child-initiated composing can be found, children may find writing a particularly compelling, if challenging, new tool for their symbolic repertoire. With that repertoire, they can negotiate, sustain, and manage relationships, replay scenes and imagine encounters, capture the music of language, and reconstruct and reimagine their worlds. Energized by participation in a composing practice they judge relevant, young children have reasons to grapple with the complexities of writing.

CHRONIC ILLNESS

The term *chronic illness* refers to a health condition that is of long duration (often defined as 6 months or more), which rarely resolves without medical or other intervention, is rarely completely cured, and is often associated with functional impairment or long-term disability. Chronic illness may be thought of as an umbrella term that refers to children who are living with a chronic health condition regardless of whether they are well or ill at any given time. The incidence and prevalence of children living with chronic illness are increasing, both because of a current rise in the incidence of certain long-term conditions such as

diabetes, asthma, and allergy, and because of rapid improvements in medical care over the past few decades, leading to improved rates of recovery from serious illness and injuries and longer life expectancy for children with many inherited conditions. It is likely that all professionals working in the field of early childhood education and care will be responsible for a child with a chronic illness at some time.

The importance of normal developmental trajectories in early childhood has been well demonstrated, yet for the child with a chronic illness, extra assistance and support may be required to ensure that expected developmental milestones are met.

The term *chronic illness* covers many different conditions, with different consequences for the child and his or her family, and it can be difficult for educators to know how to manage a child's specific health and support needs. Common chronic conditions in early childhood include the following:

- Asthma
- Cancer
- Cerebral palsy
- Consequences of low birth weight and prematurity
- Cystic fibrosis
- Developmental disabilities, including attention-deficit/hyperactivity disorder (ADHD) and autism spectrum disorder
- Diabetes
- Mental illnesses
- Obesity
- Traumatic injury, especially to the head, brain, or spinal cord.

Many of these conditions require specialized medical care, whereas others are generally managed in the community and at home.

Although specific symptoms, treatments, and management of each condition differ, there are many similarities involved in dealing with childhood chronic illness. Children with chronic illnesses face a higher than average risk of educational underachievement and premature disengagement from school and are more likely to engage in

risk-taking behaviors in adolescence. Ensuring that children with chronic illnesses remain connected to appropriate learning pathways is a key responsibility of early childhood educators. Factors associated with childhood chronic illness that may impact the child's development include the following:

- Missed opportunities for participation in early learning programs such as playgroups, kindergarten, and early school because of risk of infection or hospitalization
- Family stress
- "Invisible" consequences such as fatigue, cognitive impairment, or learning and attention difficulties
- Risk of teasing, bullying, or rejection by peers because of perceived difference
- Physical frailty and/or disability, resulting in reduced opportunities for physical growth, development, and learning

Educators and caregivers should also be aware that children living in poverty, children from particular ethnic backgrounds, and children living in poor or chaotic home environments are also more likely than other children to experience chronic illness. Children with chronic illnesses are also more likely to experience mental health problems such as depression and anxiety than their peers without a chronic illness.

Despite living with a chronic illness, however, every child still has a right to education and learning, even if he or she may be absent from the regular education and care setting for significant periods. There is a strong interrelationship between health, education, and well-being, and having a chronic illness can interfere with a child's development of strong peer and social relationships. Extra effort may be needed to keep children with chronic illnesses connected socially to friends and peers and to keep them informed of what happens if they miss out on their regular activities. At the same time, early childhood services can provide a sense of normality to a chronically ill child, and the child may not want or need to be singled out as "special" or "different" from the other children.

Achieving this sense of connectedness and improving communication between family, the early years setting, and the health care team requires high-level communication and collaboration among stakeholders. All members of the child's care team need to be working together to ensure best outcomes for the child. This may include making sure that the child has access to all the support services available in the local area, including educational, medical, allied health, respite, and social support services. Additional resources may be available to support the child in the education and care setting. Early childhood education and care staff cannot be sure that parents will know what services are available, so it is important that professional staff work together to support families and help coordinate care.

To do this effectively, information must be shared and communicated openly, but this also needs to be done sensitively. It is essential that the child and his or her family's right to privacy and control be respected. In many cultures and communities there may be stigma around particular conditions, so sensitivity may be required in order to get the appropriate information to the correct people.

Families may need to be in control of which information is shared with which other people. Educators and professional staff may need to ask themselves: What is appropriate to tell other children in the setting? What is appropriate for other staff not directly involved in the child's care? What about other families? Working closely with the child's family will help guide educators to make appropriate decisions in each case. It is also a good idea to have a written document that outlines the components of the child's daily care and management, as well as what to do in an emergency and who to contact. It is also critical that services be prepared for casual relief staff so that they also are aware of the child's needs on a daily basis.

As the rates of children living with chronic illness increase, educators and caregivers in the early years are increasingly responsible for ensuring the inclusion of these children in developmentally appropriate opportunities for playing, learning,

and growing alongside their healthy peers. With careful planning and open communication, there should be no reason for any child living with a chronic illness failing to reach his or her full educational potential.

CLASSROOM ASSESSMENT SCORING SYSTEM

The Classroom Assessment Scoring System (CLASS) is a widely used observational tool focused on providing information about the quality of early childhood classrooms. The CLASS examines quality in early childhood classrooms in terms of teacher–child interactions. Several tools and methods exist to assess various aspects of quality in early childhood education classrooms; the CLASS focuses on the process variables related

to teacher–child interactions. Several different dimensions of behavior between teachers and children and among children can be assessed using the CLASS in classrooms contexts serving young children. There are different versions of the CLASS used with classrooms serving different ages of children ranging from classrooms for infants to secondary classrooms. Although the examples and contexts differ across age levels, several core dimensions are similar across versions.

Increasing numbers of young children are enrolled in early childhood education classrooms for significant periods of their day. Being able to reliably assess teacher–child interactions using a research-driven measure is important because the experiences children have in these settings can vary dramatically. And, in fact, descriptive data indicate that many early childhood settings are of low or moderate quality. Because empirical evidence suggests that the experiences young children have in these settings contributes to a range of social and academic outcomes in the short and long term, understanding the quality of these settings is critical for addressing children’s development and learning. The interactions that young children have are paramount to their development across social and academic domains; these interactions with teachers in classrooms and peers can provide the foundation for learning throughout formal schooling.

Understanding the quality of these classrooms provides important information relevant to parents, providers, and policy makers. The CLASS can be part of a quality rating and improvement system (QRIS), which is a state system created to provide parents with information about the quality of early childhood programs in their state. Information gathered within QRISs is also intended to improve experiences for children and families enrolled in early education programs, so valid and reliable assessment of programs is necessary.

The CLASS also can be used for professional development at both the preservice and in-service level. Increasing numbers of institutions of higher education are using the CLASS as a framework for teacher preparation programs helping students to understand the importance of interactions and

specific behaviors that contribute to positive interactions and experiences for young children. Having the content of child development and teaching methods is important in teacher development. And, understanding how to implement teaching practices can provide additional support in the classroom, contributing to positive outcomes for children. Programs also can use the CLASS to provide in-service training to current teachers to consider their current practices and the interactions they have on a daily basis with the children in their classroom. Support of teachers can help teachers focus and improve in areas that are challenging for them and build in their areas of strength. Appropriate training and use of the measure allows administrators and practitioners to use a common language and common lens to focus on teacher–child interactions and work to improve classroom experiences for young children.

Description of Structural and Process Features of Early Education Classrooms

Early childhood education is complex. A multitude of adults, such as administrators, teachers, and family members, are involved in early childhood education. In addition, classrooms can have 15 to 20 or more children in them. The dynamics of what happens in classrooms is fascinating yet challenging. Teachers are responding to multiple needs of multiple and diverse children and their families. Early childhood classrooms are described often in terms of structural features and process features. The structural features may include the actual physical setting of the classroom and outdoor environment, the materials, and the education and qualifications of the teachers and director. The process variables are generally described as what actually goes on in the classroom. Whereas the structural features may address questions of *what* and *who* is available in the classroom, the process features focus on *how* these materials and resources are used and how the teacher uses his or her knowledge and expertise to nurture and support young children and facilitate children’s learning and activity in the classroom. For example,

teachers may have activities and materials for the children to use, but the process features will focus on how the teachers uses the materials and facilitate children's opportunities for learning during the activity.

Capturing and quantifying process variables in classrooms are challenging endeavors—classrooms are complex systems and observing behaviors in classrooms is complex. It is far easier to count the number of books or puzzles in a classrooms or the presence or absence of specific routines than it is to evaluate teachers' facilitation of activities and responses to children. The CLASS focuses on the process variables across 10 dimensions: positive climate, negative climate, teacher sensitivity, regard for student perspectives, behavior management, productivity, instructional learning formats, concept development, quality of feedback, and language modeling. All of these dimensions are focused on how the teacher and children are interacting with one another, and some include peer interactions. Within each of these dimensions there are multiple indicators supporting and defining the dimension, and descriptions of behavioral markers to provide examples of behaviors that contribute to ratings of each dimension. The CLASS requires that teachers' behaviors and children's behaviors are observed for several cycles and notes are taken focused on behavioral evidence observed so that a rating from 1 to 7 can be given for each dimension. The observation of these behaviors focuses on the occurrence or absence of behaviors and the depth, frequency, and intensity of the behaviors that contribute to the rating of each dimension.

The 10 dimensions are grouped into three domains: emotional support, organization climate, and instructional support. The domain of emotional support is focused on the responsive care and interactions teachers have with children and the opportunities children have to initiate and direct their activities and participation in activities and routines. Within the domain of emotional support are the dimensions of positive climate, negative climate, teacher sensitivity, and regard for student perspectives. Each indicator provides guidance for observations and note taking of behaviors in the classroom.

Emotional Support

Positive climate includes four specific indicators: relationship, positive affect, positive communication, and respect. A classroom rated high on positive climate will have evidence of teachers smiling with children, using children's names, being in close proximity to children, and having social conversation.

Negative climate also has four indicators: negative affect, punitive control, sarcasm/disrespect, and severe negativity. Negative climate focuses on expressed negativity in the classroom and the intensity and/or escalation of negativity in the classroom.

Teacher sensitivity has four indicators: awareness, responsiveness, addresses problems, and student comfort. A classroom high on teacher sensitivity has a teacher who is aware of children's emotional and cognitive needs, addresses their problems and struggles in a timely manner, and successfully helps children to resolve problems so that children can reengage in activities and classroom routines.

The last dimension within emotional support is regard for student perspectives. Four indicators comprise regard for student perspectives: flexibility and student focus, support for autonomy and leadership, student expression, and restriction of movement. Classrooms rated high on regard for student perspectives have teachers who follow children's lead, elicit ideas from children, and support children to be independent in activities and tasks.

Organization Climate

The domain of organization climate is about organizing the environment and activities within the environment to promote optimal participation and learning opportunities. Within the domain of organization climate are the dimensions of behavior management, productivity, and instructional learning formats. Behavior management centers on setting behavioral expectations for children, following through, and providing guidance so that children are appropriately engaged in activities and the routines of the classroom. Productivity also relates to children's involvement in classroom

activities and routines and focuses on how the teacher manages his or her time and schedule so that learning opportunities are optimized. Finally, facilitation of learning and development is a core component of effective teaching and focuses on the strategies and techniques that teachers use to engage children in classroom activities and routines and opportunities for learning within these contexts.

The instructional support domain centers on what teachers are doing, including questioning, feedback, and language to promote children's learning, thinking, and understanding. Within this domain are the dimensions of concept development, quality of feedback, and language modeling. Concept development intends to move teachers away from rote drill and recall activities and to use strategies to support children to think, problem solve, and develop higher order thinking skills. Through skillful questioning and integrating concepts, teachers can support children in learning how to think and focus on understanding—ultimately supporting children to learn how to learn.

Four indicators comprise the dimension of concept development: analysis and reasoning, creating, integration, and connections to the real world. Classrooms rated high on concept development have teachers who ask open-ended questions, provide children opportunities to brainstorm and plan, and make explicit connections for children between what they are talking about and learning in the classroom to their own lives and to previous learning. Quality of feedback centers on feedback teachers provide to children to expand their learning and participation in activities. High-quality feedback that goes beyond merely yes or no comments, which curtail activities or sends a message to children that they are finished, can further engage children in the activities and supports their persistence in activities and with projects. And finally, language modeling describes the language teachers use in the classroom for language stimulation and language facilitation, so that children have opportunities to be exposed to language and opportunities to use language. The indicators within language modeling

are frequent conversation, open-ended questions, repetition and extension, self- and parallel talk, and advanced language. Classrooms rated high on language modeling will have teachers who engage children in conversations, allow children time and space to use their language, ask questions and provide opportunities for children to use language beyond one or two words to respond to these questions, repeat what children say and extend their words and language, and describe their own actions and the actions of children with words. In addition, teachers and children in these classrooms use descriptive language in the classroom.

Research

Experiences children have in child care are associated with positive academic and social outcomes. Repeatedly research has provided evidence that positive and responsive interactions with children provide children the nurturing and security to explore their environment, interact with materials and peers, and learn and develop within the classroom context. These interactions with adults and peers in the classroom can serve as the foundation for learning and development, and the effects of early positive interactions can persist into early elementary grades.

Teacher behaviors focused on behavior guidance and management are related to children's self-regulation. Self-regulation helps children focus on learning and appropriate interactions with peers and teachers in the classroom. Children know what is expected in the classroom and receive positive reinforcement for meeting expectations, have learning opportunities, and have teachers who facilitate activities to maximize children's interest and engagement. Within the classroom context, the interactions adults have with children can facilitate children's learning. Although teachers are responsible for planning and implementing activities, the activities alone are not sufficient to promote and support children's learning. Teachers' facilitation, questioning, and participation in activities are key components in supporting children's engagement and learning during activities and routines.

Interactions focused on instructional support also provide support for children's learning in terms of higher order thinking, persistence, and language development. Asking children questions and providing opportunities that focus on developing children's higher order thinking skills and understanding are critical to children's learning. Feedback that assists children to expand their learning and supports their efforts within activities and tasks is critical to their continued involvement in activities. Continued and extended participation in activities is associated with children's learning. Rich language use in the classroom, conversations, pairing language with actions, and using descriptive language provide children exposure to language and opportunities to use language that contribute to children's language development.

Although these types of teacher behaviors in classrooms are associated with positive outcomes for children, research has revealed that these teacher behaviors happen at relatively low levels in early childhood classrooms. Observations in thousands of classrooms indicate that although teachers often have positive interactions that are responsive to children's needs and acknowledge their interests and ideas, interactions that facilitate children's higher order thinking and understanding, provide extended feedback that offers opportunities for additional learning, and model rich extended language occur less frequently.

Of note is that these adult-child interactions can be improved with professional development and support. Current research suggests that teachers who attend trainings focused on the teacher-child interactions included in the CLASS and are provided additional support and coaching can improve the interactions they have with children. These changes in interactions may at first appear to be small, but a small change in interactions has significant influence on children's learning and outcomes.

Importance of the CLASS to Parents, Providers, and Policy Makers

Information about the CLASS is important to parents, providers, and policy makers for a number of

reasons. First, information gained from assessing teacher-child interactions provides parents information about the quality and the effectiveness of teachers in classrooms of young children. This information can serve as one indicator of the overall quality of the classroom and the experiences their child may have in different classrooms. Choices about what to include in QRISs that evaluate the quality of early care and education programs are made at the state level, and several states have included the CLASS in their QRIS. The QRIS is intended to help define the quality of early childhood programs, provide information for parents to help them make informed choices about early childhood education programs for their children, and establish a foundation for a high-quality early care and education system. These systems provide parents information overall about the program, and the inclusion of the CLASS provides parents information specifically about the experiences around interactions that their child may have in the classrooms.

Providers can use the CLASS in a variety of ways. Teaching is a complex endeavor and high-quality early childhood education is comprised of multiple components. One way to assess effective teaching is to use the CLASS to examine teacher-child interactions. Providers can use the CLASS within their program to evaluate teachers, to provide feedback to teachers, and to help assess professional development needs for teachers in their programs. The CLASS provides a framework through the use of the three domains—emotional support, classroom organization, and instructional support—for providers to examine the effectiveness of their teaching. CLASS observers are trained to reliably assess teacher-child interactions in classrooms. In programs in which the language of the CLASS is shared among administrators and teachers, the CLASS provides a common language to examine teacher behaviors.

Teachers may have clarity on what is being observed and evaluated and descriptions of behavior through the behavioral markers that support each indicator. For example, if a teacher is struggling in the area of concept development, they can look at the indicators, read the descriptions of the

behavioral markers, reflect on their interactions, and be provided ideas to use to change and improve their interactions in the area of concept development. Overall program administrators can examine their classrooms in terms of the CLASS and consider the area of emphasis for professional development. If most of the classrooms have high ratings across the indicators on classroom organization and lower scores on instructional support, the administrators can focus professional development on areas related to questioning, feedback, and language rather than time management, planning, and behavior management.

Finally, using the CLASS, and the framework for observing effective teaching it provides, is useful to policy makers for several reasons. The field of early childhood education is relatively new. Although Head Start has been in existence for several decades, state-funded prekindergarten programs are a recent development, and the number of child care programs for infants and toddlers is increasing as benefits of early education are realized and as more families have adults working outside the home and need care for their children. Many programs began without the evidence of what works for children, definitions of quality, and data about effective teaching. As this type of evidence is accurately and systematically collected, there are significant amounts of data to process and analyze and much is to be learned about what is quality and how to develop and support effective teaching in the classroom for young children. The CLASS provides one lens of quality to assist in these endeavors.

CLASSROOM PROCESSES

Examining the qualities of schools and classrooms that affect children's development has become one of the most important pursuits in educational

research today. Classrooms provide the context in which children learn and develop. Children do not learn simply by sitting in a classroom. Rather, the interactions that children engage in with teachers, peers, and tasks are the force that propels children to develop. Much research has been undertaken to increase understanding of these classroom processes. This entry focuses on the classroom processes that take place in typical preschool classrooms. Given the fact that, at least in early childhood, teachers structure the environment and are the primary drivers of the interactions that take place, the entry places special emphasis on the interactions that children have with teachers within the classroom.

Transactional Views of the Classroom Environment

There are two complimentary views of the transactional nature of classrooms. Urie Bronfenbrenner's bioecological model of human development describes several salient aspects of classrooms. First and foremost, the bioecological model emphasizes the proximal processes that are primarily responsible for development. Proximal processes are the regularly occurring, increasingly complex, reciprocal interactions that take place between a person and that person's environment—in this case, teachers, peers, and tasks. Thus, those who want to understand development need to understand the nature and quality of interactions children have on a regular basis. The bioecological model also delineates the environment into strata that help to define the more important and less important aspects of the child's environment. People whom the child interacts with more will generally have a bigger influence than people whom the child interacts with less. Furthermore, the characteristics of the child and the time frame of the interactions are seen to modify the proximal processes. For example, a shy child will experience the classroom differently than an exuberant child, and a child today experiences a different classroom than a child from a generation ago.

This view of children and classrooms is entirely consonant with Arnold Sameroff's transactional model of development. This view emphasizes how the person has an impact on the environment and the environment has an impact on the person. Furthermore, understanding development means more than just understanding aspects of the child. Sameroff emphasizes that focusing only on the characteristics of a child without taking into account the context will be misleading. Thus, the Sameroff view also emphasizes the dual roles of student and classroom in understanding development.

Supports Given to Classrooms of Children

Although there are several, one of the most prominent views of classroom interactions emanates from a measure of classroom process, the Classroom Assessment Scoring System (CLASS), developed by Robert Pianta and colleagues. This measure, and its corresponding framework, divides interactions between teachers and children into three types: emotional support, classroom organization, and instructional support. The CLASS measure itself has gained much notoriety in recent years given its use not only in research but also in its use in evaluating program, center, and classroom quality. Thus, it is helpful to understand a little about how the CLASS views classroom processes.

When walking into a preschool classroom, evidence of emotional support is often most prominent. Emotional support refers to the emotional climate of the classroom and is the domain of teacher-child interactions that supports children's emotional well-being and sense of belonging. How would a child feel when in this classroom? Are there positive emotions expressed? Does the teacher know the children as individuals? Emotional support also extends into aspects of the classroom that seem less emotional but are nonetheless important for children, as those aspects can also communicate respect, connections between and among children, and interactions within classroom practices. These aspects include the degree to which children are given autonomy in the classroom to pursue their own interests (e.g., given a

choice of centers) and have responsibility (e.g., organizing the bookshelf). Classroom emotional support and its components have been linked to a wide variety of positive outcomes, including increased competence, decreased problem behaviors, and even academic achievement. Furthermore, the within-day consistency of emotional support (above and beyond its average levels) has been linked to positive social-emotional and academic outcomes as well. Generally, high levels of emotional support are seen in preschool classrooms as measured by the CLASS.

Classroom organization has to do with managing the demands of running a classroom. Teachers can spend a lot of time dealing with behavior problems or transitioning between activities. When classrooms are organized, they function like well-oiled machines, often through the effective use of routines to maximize the learning time for students. For example, ringing a bell to start a transition can signal that it is time to clean up. Notably, routines may take time to set in place, but once they are, they can save a lot of time over the course of the year given how frequently classrooms transition between activities. Likewise, children's behavior problems can quickly derail optimal classroom functioning. However, teachers can proactively manage classroom behavior by anticipating situations that may be problematic (for some children) and by effectively working to help children through the potentially difficult situation. For example, if using the computer is a center activity in which children will argue over whose turn it is, having an organized rotation, a timer, or other regulatory strategy can manage the problem before it happens. Classroom organization and its components have been linked to children's development of self-regulation. Generally, moderately high levels of classroom organization are seen in preschool classrooms as measured by the CLASS.

Instructional support is the aspect of classroom interactions that has to do with conveying content knowledge. Although the content can vary from classroom to classroom and over the course of the year, generally, instructional support includes the cognitive demands that are being placed on the

students. This can be done through asking questions, asking students to predict, providing feedback that helps students engage in the classroom, and using age-appropriate advanced language. In a preschool classroom, this may be done by didactically teaching content or by having discussions with individual children. Generally, moderately low levels of instructional support are seen in preschool classrooms as measured by the CLASS.

It is worth noting that these three aspects of teacher-provided classroom quality are interrelated. Teachers who offer more emotional support at a given time are also likely to offer more classroom organization, and so on. Furthermore, there are relations to one another in how they play out over the course of a day, whereby emotional support is positively related to later classroom organization and vice versa. And there are indications that there are also relations to one another over the course of a year (at least in elementary classrooms), whereby more emotional support is positively related to later instructional support and vice versa. For this reason, new approaches have been developed that view a core part of teachers' interactions that cuts across all these domains while also allowing for there to be differences in domains. From this perspective, there is an overall responsive teaching component, with two specific domains called (1) proactive management and routines, and (2) cognitive facilitation (that do not include that responsive teaching component). The advantage of this approach is that it may better capture the nature of how teachers differ in their interactions with children. The difficulty of this approach, however, is that it is computationally difficult, requiring a high degree of statistical modeling to uncover these aspects of teaching.

Although not measured by the CLASS, another aspect of classrooms that may be important to consider are the activities and materials available for learning. In some instances, it may be appropriate to examine what is available to children in terms of the physical setup and materials in the classroom. Classrooms that offer many provisions for learning have many developmentally appropriate books, gross motor equipment, space for privacy, and

materials for special activities such as art, drama, math, and science. This way of viewing quality is less process oriented, but it may set the stage for certain types of interactions to occur or may hinder certain interactions from happening. Nonetheless, these provisions are consistent with the bioecological model that describes how interactions with these materials can drive development. The next section of this entry examines this aspect of classroom supports when discussing how children engage with tasks.

Supports Received by Individual Children

Another way to view classroom interactions is to look at the quality received by children instead of offered by teachers. Another measure, which also emanates from the CLASS framework, is the Individualized Classroom Assessment Scoring System (inCLASS), developed by Jason T. Downer and colleagues. The inCLASS focuses on the quality received by individual children as measured by their positive and negative engagement with teachers, peers, and tasks. Positive interactions with teachers include the extent to which there is positive engagement and communication with the teacher. Positive peer interactions include the idea of positive peer sociability, peer assertiveness, and communication. Task orientation includes the idea of positive engagement with tasks and self-reliance. Negative aspects of these scales are also captured with conflict with teachers and peers.

Using the inCLASS, one study, by Downer and colleagues, examined what children experienced on the mean level. On a scale of 1 to 7, children scored a 3.2 on the Positive Interactions with Teachers subscale, a 3.4 on Positive Peer Interactions, a 4.6 on Task Orientation, and a 1.3 on Negative Interactions (with teachers and peers). Although helpful to understand this descriptively, it is perhaps more interesting to know that there is a wide degree of variability in what children experience in a classroom. To some extent, this variability in interaction quality may be expected when talking about how children interact with classroom tasks,

sometimes referred to as task orientation. Given the available materials, children may have to self-regulate to initiate or maintain engagement in the task, creating a situation that allows for more differences to exist.

Likewise, it is not entirely surprising that children vary in the degree to which they have positive interactions with peers. In part due to their own social-emotional competence, children may be better or worse at engaging with peers. However, what is more surprising is that two children in the same class may have substantially different experiences in their interactions with the teacher. For example, one child may best be characterized as having positive interactions with teachers, while another child in the same classroom may not.

What remains to be seen are the circumstances under which this variability across children's experiences is good (or at least not bad). For example, at-risk children benefiting more from classroom interaction quality might be seen as desirable by many. However, if certain children (e.g., those with disabilities) within a classroom seem to receive particularly poor quality interactions, then this variability across children might be seen as undesirable. Nonetheless, what is notable is that both classroom supports and child behaviors explain classroom functioning and child outcomes. By understanding the quality of supports offered and the quality of supports received (i.e., transactionally), a rich understanding of the classroom processes children experience emerges. For example, Timothy W. Curby and colleagues examined data that had CLASS measurements of the teacher and inCLASS measures of two children throughout a day. They found much evidence to support the idea that teachers' emotional support and classroom organization were associated with children's later engagement with teachers, peers, and tasks. They found that children's positive engagement with teachers was associated with better emotional support by the teacher a little later in the day and that children's negative engagement was associated with worse classroom organization a little later in the day. In particular, exploring classrooms in this

way may allow for methods to be uncovered that disrupt the negative cycle between children's negative engagement and poorer classroom organization.

Making Use of Classroom Process Data

To understand development from a transactional perspective is appealing, but there are methodological hurdles. First and foremost, identifying measures that can be administered at least three times without losing validity or changing scales or tasks is very challenging. For example, to understand child achievement over the course of a year, the test needs to be able to be given several times, without the child just learning the test itself. Multiple versions of the test may be given, but the different forms need to actually be measuring the same constructs, even though they are different versions.

Statistically, there are several approaches that may be helpful in analyzing transactional data. Sequential analysis can answer questions about how discrete events (or states) are probabilistically related to other events. For example, when a child asks a question (a specific event), what is the likelihood that the child will be responded to by the teacher (another specific event)? Sequential analysis is a good tool for dealing with questions that have to do with understanding how these events are related over time, and thus it helps researchers understand certain processes.

Perhaps the most comprehensive transactional approaches use a type of statistics called structural equation modeling (SEM). SEM allows variables to be both predictors and outcomes at the same time, as well as for there to be multiple outcomes modeled simultaneously. Within SEM, three models are generally considered best suited for modeling transactional relations, according to Emilio Ferrer and John McArdle: cross-lagged autoregressive models, bivariate growth models, and latent difference score models.

Cross-lagged autoregressive models allow for tests of directional lagged relationships. For example, does higher emotional support earlier in the day relate to better child engagement with teachers

later in the day, or does better child engagement relate to higher emotional support, or neither, or both? Notably, these models account for how the two sets of variables correlate within time and are, thus, able to isolate how the processes play out over time. Although not necessarily a requirement, these models work best when the assessments are equally spaced (e.g., a 1-hour space between each assessment time point for everyone in the sample). These models do not model whether the levels of the variables are going up or down over time. Rather, they simply ask if change in one variable is directionally associated with change in another at a later time point.

Bivariate growth models are able to model the actual changes in the levels of the variables over time (unlike cross-lagged autoregressive models). Furthermore, assessments that do not happen at equal intervals are more easily accounted for. Thus, if there is a lot of change in a variable, such as during an intervention, and measurements are not equally spaced, a bivariate latent growth model may be better suited to answer the research questions. By examining how the change in each variable (e.g., the slope of emotional support) is correlated with the other (the slope of child engagement), one can determine whether change in one variable is associated with change in another variable while also understanding how each variable changes over the course of time. However, determining directionality is not possible as with a cross-lagged autoregressive model.

Last, latent difference score models essentially combine aspects of the cross-lagged autoregressive model and the growth model. Latent difference score models capture nonlinear change while also assessing for directional change. These models are very powerful but are sufficiently complex that they are not prominent in the research literature.

CLINICAL EXPERIENCES

Clinical experiences are an essential component of an early childhood teacher preparation program. Programs use a variety of terms to describe clinical experiences: field observation, field experience, laboratory, practicum, or internship. The common factor of all of these is the opportunity

for future early childhood teachers to have authentic experiences with young children. Early clinical experiences may include observations that help teacher candidates better understand the early childhood teaching career and developmental characteristics of young children. Mid-level clinical experiences typically provide opportunities for preservice teachers to apply the theoretical principles learned in their course work to the children in a classroom setting, and a culminating clinical experience, often called “student teaching” or “laboratory capstone experience” helps beginning teachers refine their observational and instructional skills. Clinical experiences in early childhood may also be outside the classroom setting, such as with a home care provider, a home visit with an early interventionist, or in a community-based agency. This entry describes the historical trends in clinical experiences, as well as contemporary clinical models. It describes the characteristics of quality clinical experiences, including the role of the cooperating teacher and clinical supervisor, and the challenges in providing these experiences for teacher candidates.

History of Clinical Experiences

Clinical experiences (or “practice teaching”) have been a part of American teacher preparation since the early normal schools of the 1800s (so named because they were designed to establish a “norm” for education practices). As these normal schools grew into teacher colleges or universities in the early 1900s, clinical experiences remained a part of teacher training, although there was a wide variety of clinical experiences, in terms of length and requirements. The progressive education era led by John Dewey, along with the emergence of the child study movement in the early 1900s, led to the establishment of university laboratory schools that included teacher training opportunities.

Clinical experience requirements were strengthened in the 1950s and 1960s, and by 1980, most states had requirements for student teaching in licensure programs. While there has been agreement about the importance of future teachers having the

opportunity to practice their skills in a real-life setting under the guidance of a mentor, there continues to be a wide variation of implementation. The 2010 report of the Blue Ribbon Panel on Clinical Preparation and Partnerships of the National Council for the Accreditation of Teacher Education (NCATE) found that while most states required a culminating student teaching experience for certification, the experiences varied greatly, with some teacher candidates spending a year in a school setting working with an expert mentor and other teacher candidates spending as little as 8 weeks in the classroom with an inexperienced cooperating teacher.

Historically, the typical elements of a clinical experience have been observation, then tutoring individual students, and eventually taking over the classroom and “solo teaching.” Traditionally, clinical experience students worked under the guidance of a mentor teacher and were not seen as “real” teachers, even when having full responsibility for instruction. Planning, instruction, assessment, and other duties of a teacher were done in isolation by the teacher candidate, although the mentor or cooperating teacher would provide assistance and approval, as needed. Teaching experiences were scaffolded, with the novice teacher being given minimal responsibility at the beginning of the experience and gradually having full responsibility for the classroom. This traditional model drew criticism in the mid-2000s, with calls for stronger models of collaborative clinical experiences. Today’s clinical experiences continue to evolve with new models showing great promise in preparing early childhood educators.

Models and Approaches to Clinical Experiences

Research comparing models of clinical experiences is meager, and there is no definitive evidence that all clinical experiences have a positive impact on teacher candidates’ knowledge, skills, and dispositions. Clinical experiences range on a continuum from observation with high mentor teacher control to a co-taught, residency model where the teacher candidate is deeply embedded in the

school setting and shares equal responsibilities with the mentor teacher.

Laboratory School Practicum

Laboratory schools are typically associated with a college or university and have a developmental research focus, influenced by the laboratory school founded by John Dewey at the University of Chicago. Lab schools often have viewing windows or other opportunities for observation and research by early childhood preservice teachers. These students may also be placed in a classroom, working with an experienced teacher implementing classroom activities with a group or individual children. Candidates may also spend more than one semester with the same children, “looping” or following them as they move to another classroom. Informal observational assessments of children are a regular part of the clinical experience, and early childhood preservice teachers often gain a strong understanding of child development characteristics through a lab school practicum.

Traditional Clinical Sites and Educator Preparation Partnerships

A vast majority of early childhood clinical experiences occur in settings other than colleges and universities. Teacher candidates may be placed in a Head Start program, a child care program, a private or public preschool, or a kindergarten–third grade (K–3) classroom. The National Association for the Education of Young Children (NAEYC) 2010 accreditation standards for early childhood professional preparation programs require that programs provide opportunities for candidates to observe and practice in at least two of these settings with at least two differing age groups (infants/toddlers, preschool–kindergarten, or K–3). Candidates should also be exposed to diversity in terms of race, ethnicity, language, socioeconomic status, and children’s abilities and disabilities.

These clinical experiences require partnerships between the teacher preparation program and the clinical setting. Often memorandums of understanding are used to clarify the roles and

responsibilities of individuals in the clinical experience triad, that is, the cooperating teacher, university supervisor, and teacher candidate. Teachers and administrators from the clinical site may serve on advisory committees for the preparation program, providing feedback that shapes the clinical experience requirements. Cooperating teachers may receive stipends for their service and have professional development opportunities with the university or college. In these clinical experiences, the teacher candidate may have paired curriculum methods courses that require assignments to be completed in the field, such as an early literacy course with accompanying assignments to do literacy-based activities and assessments with young children. In recent years, there has been debate about breadth versus depth in clinical experiences, or whether it is more beneficial for teacher candidates to have a wide variety of shorter field experiences or longer, more in-depth experiences in one setting. Whereas traditional clinical experience partnerships may provide a variety of settings, professional development schools and residency models offer more in-depth experiences for teacher candidates.

Professional Development Schools

Professional development schools (PDSs) first emerged in the mid-1980s and have since proven to be an effective clinical experience model, not only for educator preparation but also for the positive impact on the clinical setting. In a PDS model, the clinical site and educator preparation programs form a strong partnership that is based on mutual respect, accountability, and shared philosophy. NCATE defined the mission of PDSs as being more than just giving teacher candidates a quality clinical experience, but also as improving students' learning, providing opportunities for faculty and clinical teachers' professional development, and offering a rich setting for shared research.

In a PDS model, college or university courses may be taught on-site, with teacher candidates then having the opportunity to immediately apply the knowledge they're learning in their assigned classroom. Faculty may model instructional strategies

for both the cooperating teacher and teacher candidates or co-teach with the classroom teacher. Teacher candidates are in the building often and fully participate in the school community activities, such as attending parent-teacher conferences, family events, and teachers' meetings. Joint research may be conducted, with the preparation program's supervisor, mentor teacher, and teacher candidates all sharing decision making about children's learning opportunities. The college or university may also offer professional development opportunities for the PDS's classroom teachers, either through workshops, conferences, or tuition-discounted courses. With a focus on inquiry and reflective practice, a PDS model can improve the knowledge and practices of teacher candidates, new and veteran teachers, and college/university instructors. For a PDS partnership to be successful, regular formal meetings and informal discussions must occur between the educator preparation program and the PDS site, with agreements about shared resources, evaluation measures, roles and responsibilities of teacher candidates, classroom teachers, and educational methods faculty. These discussions are often facilitated by a university/college site coordinator or liaison.

Residency Models

One of the newest innovations in clinical experiences is the teacher residency model. Residency programs, often in urban high-need school districts, typically offer an initial teaching certification at the master's degree level. Residents take course work while also working in a classroom for the entire school year as an apprentice. Residents teach under the supervision and coaching of a carefully chosen, experienced, master teacher. The residency model focuses on teaching, reflection, and collaboration, with a primary emphasis on understanding the urban school environment.

Course work, often done with a cohort group, helps residents bridge the gap between theory and practice. Residents are evaluated on the same standards as the district's classroom teachers. Residents commit to remain and teach in the urban school district and continue to receive coaching

and feedback on their first two years of teaching; this coaching and feedback provides a strong induction model. For this 3-year commitment, residents receive a stipend during their apprenticeship and may also have reduced or free graduate school tuition. The Urban Teacher Residency United organization reported that research has shown that 85% of teacher candidates who complete an urban teacher residency program remain in that school district after their 3-year commitment is over. Programs such as the Boston Teacher Residency and Chicago's Academy of Urban School Leadership have been cited as national models of excellence in clinical experiences.

Co-Teaching

The co-teaching approach to clinical experiences may be used in any of the models described earlier. It is an approach that redefines the traditional roles and responsibilities of the teacher candidate and cooperating teacher in the clinical setting. With its roots in special education and based on the work of Marilyn Friend and Lynne Cook, co-teaching is defined as the cooperating teacher and teacher candidate having equal roles and responsibilities for planning, instruction, and assessment from the first day of the clinical experience. Co-teaching strategies include the following:

- One teach, one observe
- One teach, one assist
- Station teaching
- Parallel teaching
- Supplemental teaching
- Differentiated teaching
- Team teaching

The cooperating teacher and teacher candidate plan together, choosing the strategies that best help children learn the content of the lessons, with equal participation by both. Responsibility is also shared for assessment of students. Teacher candidates also have opportunities for "solo" teaching, and some educator programs place two teacher candidates in the same classroom, allowing them to co-teach and do peer evaluations of each other's

solo teaching lessons. Co-teaching strategies allow for smaller group instruction, more individual help, and better guidance and classroom management, and strengthen teacher candidates' collaboration skills. Funded by a U.S. Department of Education grant, the St. Cloud State University College of Education conducted a 4-year research project examining the effectiveness of co-teaching in clinical experiences and found that co-teaching positively impacted reading and math achievement of K–12 students, as well as teacher candidates' instructional and management skills. Cooperating teachers also reported being able to better meet the needs of all students, especially those with high learning needs.

Roles of Cooperating Teachers and University/College Supervisors

Regardless of the model or approach used, clinical experiences are dependent on the effectiveness of the mentor or cooperating teacher and the educator preparation program supervisor. The criteria to become a cooperating teacher vary across states from no specific requirements to a rigorous screening process and advanced degree. Some educator preparation programs may provide additional training or orientation to the expectations of a cooperating teacher. A key component to successful clinical experiences for future early childhood educators is the mentor teacher. This teacher provides a model of quality instruction and assessment practices, while also providing support for the novice teacher's efforts. The cooperating teacher must also have strong communication and collaboration skills and a positive attitude about teaching and young children.

The university/college supervisor also plays an important role in the clinical experience. Typically supervisors will meet with teacher candidates regularly to give informal support and also provide formal coaching of instruction. This may include a pre-observation conference, an observation of teaching skills, and a post-conference mentoring session of constructive feedback, focusing on the impact the candidate's instruction had on the children's learning and development. The supervisor

may also choose to co-teach or demonstrate a strategy for the teacher candidate. The level of support needed is dictated by the needs of the teacher candidate. Helping teacher candidates make a connection between their course work and clinical experiences, as well as reflect about their practice, is also a part of the supervisor's role. Technology may provide additional supervision opportunities with observations and conferences done via webcams, as well as online public or private discussion boards.

Characteristics of High-Quality Clinical Experiences

As noted previously, there is a great range of variability among clinical experiences in early childhood education, in terms of length of time, types of settings, expectations for teacher candidates and cooperating teachers, supervision, and support. However, guidelines such as NAEYC's 2010 standards for early childhood professional preparation and the Blue Ribbon Panel on Clinical Preparation and Partnerships 2010 report provide characteristics of high-quality clinical experiences. These characteristics include the following:

- A focus on children's learning and development in clinical experience policies and practices
- A strong connection between academic course work, both theory and methodology, and clinical experience assignments and supervision, with the opportunity to compare observed practices to defined standards of quality early childhood education
- Well-planned and sequenced fieldwork that scaffolds teacher candidates' skills and knowledge
- Evaluation of teacher candidates, the clinical setting, and the impact teacher candidates are having on children's learning and development
- Mentor teachers chosen based on well-defined criteria of excellence and who model practices consistent with early childhood professional standards
- Opportunities to observe exemplary mentor teachers and have ongoing dialogue with them about instructional decisions

- Opportunities to demonstrate academic content knowledge and understanding of children's developmental characteristics
- Opportunities to practice instructional, guidance/discipline, and assessment skills
- Regular, ongoing constructive feedback from both the mentor teacher and the university/college supervisor
- A reflective model that requires candidates to regularly consider the effectiveness of their actions on children's learning and development
- A professional learning community that models best policies and practices and welcomes the teacher candidate as a participating member of the community, including opportunities to interact and learn from supporting staff, such as counselors and therapists
- Adequate resources, including technology, and a fully staffed setting with qualified personnel
- Opportunities for inquiry and research within the classroom setting and with individual children

Challenge of Finding High-Quality Clinical Settings

While early childhood education offers a wide range of opportunities for clinical experiences, there is also a challenge in finding high-quality settings in all age levels and types of settings. In many areas of the country, there is a lack of quality infant/toddler settings, and child care centers or preschools may lack highly qualified teachers and resources. With the increased pressure for accountability and rigorous academic standards that do not address social and emotional development, primary grade classrooms are often models of developmentally inappropriate practices. One way to address this challenge is to "flood" quality sites and exemplary cooperating teachers' classrooms with multiple teacher candidates in the same classroom for extended placements. Educator preparation programs may also partner with high-need schools or programs and work collaboratively to raise the quality through joint professional development and improvement plans. Finally, if a clinical experience setting does not meet the characteristics of a high-quality setting, educator

preparation programs must provide other examples or experiences for candidates.

CLOSE OBSERVATION OF CHILDREN LEADS TO POWERFUL CURRICULUM: SYLVIA ASHTON-WARNER

Sylvia Ashton-Warner (1908–1984) was a woman of many passions, and her greatest was figuring out how to teach young children effectively. Her major contribution to early childhood education, now recognized and replicated in many countries around the world, was the invention of Key Words, also called Organic Reading or Key Vocabulary, a compelling way of introducing young children to reading English. Ashton-Warner was a White woman, born in New Zealand. She struggled to teach with respect, to avoid the colonialism and racism that was then the practice of the segregated New Zealand school system. She kept extensive journals as she explored how to do this and, later in her life, wrote 11 fiction and nonfiction books, which have been translated into more than 17 languages.

Her life was portrayed in two commercial movies: *Two Loves* (1969) and *Sylvia* (1985). *Two Loves* (called *Spinster* in New Zealand) starred Shirley MacLaine. The director cast Hawaiian children as Maori children. This displeased Ashton-Warner and she refused to see the movie. By contrast, *Sylvia* was rated by *Village Voice* reviewer Andrew Sarris as “one of the ten best films of 1985.” *Sylvia* starred Eleanor David, Nigel Terry, and Tom Wilkinson. Director Michael Firth consulted with Ashton-Warner as he conceptualized the film.

Ashton-Warner grew up in a large, poor family. Her father, crippled by arthritis, stayed at home, cooking for the family and telling stories to his children. Her mother was a rural teacher, the family's wage-earner, unskilled, and strict in the "be silent, face front, recite!" way. When left-handed Sylvia was her pupil, her mother pinned her left sleeve behind her, forcing her to use her right hand. Perhaps as a result of this restriction, eyewitnesses report that as an adult Ashton-Warner was able to write a sentence on the chalkboard with one hand starting at the first letter and the other simultaneously writing backward from the period! She could also draw two animals at the same time on the chalkboard, one with each hand.

Ashton-Warner's parents had earlier had another baby they called Sylvia, who died at birth. Ashton-Warner grew up burdened with the awareness of this dead sister who shared her name.

In addition to teaching children in New Zealand and later in Colorado, United States (1970–1971) and Vancouver, British Columbia, Canada (1971–1973), Ashton-Warner wrote fiction and nonfiction books, and she taught adults in Aspen, Colorado, and in Vancouver. In teacher training school she met and later married Keith Henderson. During their courtship she sent him paintings, which she recalled in her memoir *I Passed This Way* finding 40 years later in his desk. Henderson and Ashton-Warner worked together, he as headmaster, she as infant mistress (the title at that time in New Zealand for the teacher of the youngest class, those younger than age 6). Married couples like them were permitted to teach together only in Maori schools.

During all of her teaching (1932–1960), except in Colorado, the children Ashton-Warner taught were Maori. Ashton-Warner was White, and the cultural gulf was large. It wasn't until 1949 that Ashton-Warner developed Key Vocabulary, but she had been seeking ways to bridge cultures, learning the Maori language and exploring the importance of music and art in their culture, since her earliest days of teaching. The Key Words method is Ashton-Warner's best known contribution but not her only contribution. She spent a great deal of time writing in her journal and considering what she saw and

heard in her classroom, trying to make it better—more responsive to children's needs and more likely to provoke their best efforts. Ashton-Warner was focused on understanding children. She observed and recorded what they did, what they said, what lit them up, and what turned them off.

Ashton-Warner learned to recognize that young children come to school full of material, bursting to tell others about it, like suitcases stuffed so full you must sit on them to close them. She pieced together from these observations that the first order of business in her teaching day would be to let the children "breathe out" the material they brought from home, so there would be room for her to put in some more material—which they would "breathe in." Mindful of this, she scheduled each day to alternate between times of children expressing what they brought with them, and times when she could ask them to bring active attention to what she was teaching. She organized times and spaces each day, aiming for choices that were productive, expressive, and useful, and also so that the children's creativity was supported by ample time and materials.

Ashton-Warner divided the school day into four periods, each lasting between 1.5 and 2 hours. Going against all tradition, the first period in the morning and the first period in the afternoon engaged children in all things creative, play before work, as shocking as offering dessert before spinach. This helped alleviate a problem teachers face: People (at any age) tend to behave badly when asked to do things that don't interest them and that they haven't chosen. But after they have had time to choose and to express themselves, they more comfortably pay attention to what society has asked the teacher to teach them.

Ashton-Warner's intention, coming out of her experience of World War II, was always to teach children to be peaceful, a complicated goal among Maori people who value fierceness, especially in their boys and men. She wrote often about the child as a volcano, with only one vent—angry explosion—for relief of the internal pressure. The teacher's job was to open a second vent—peaceful creativity. Believing this, she daily offered children

the arts: clay, paint, dancing, singing, and drawing—things she herself had learned to use after a debilitating “mental breakdown” from 1938 to 1939 during which she was treated and educated about psychology by a supportive neurologist. She played piano and painted and drew very well.

This movement of thought—from wanting peaceful children to offering them the arts so they would express violent feelings nonviolently—would appear in the work with young children in the city of Reggio Emilia, Italy (also beginning immediately after the end of World War II) and can be traced through 20th-century thinkers John Dewey and Sir Herbert Read, all the way back to Plato. Ashton-Warner was a reader, a lifelong student. She paid attention to these theorists and was scientific, integrating what she learned from her observations of the children and the community into her curriculum. She was deeply influenced by Read’s writing, which was being promoted by the Department of Education in New Zealand during her teacher training. Read sums up his belief in this way:

What I have in my own mind is a complete fusion of the two concepts, so that when I speak of art I mean an educational process, a process of upbringing; and when I speak of education I mean an artistic process, a process of self-creation. (Read, 1966, p. xxiii)

New Zealand schools were segregated during Ashton-Warner’s teaching life, with White schools teaching a fundamentally European/North American curriculum, and Maori schools teaching, but less successfully, the same curriculum. Ashton-Warner was firmly committed to letting children be themselves, not trying to change them into cookie-cutter copies who would meet official standards. Her “follow the child” beliefs moved her to design ways to serve children’s interests and needs; all of this was opposite of the teacher-in-front-of-the-class style of teaching that was prescribed in schools like hers at that time. She saw children as people with their own interests, who could be taught skills through those passionate interests.

Always in creative ferment, Ashton-Warner urgently needed quiet time—for playing music and painting and for designing work for the classroom—away from her own three children and husband. From her earliest teaching she found or made herself time and private places to reflect on what she had seen and heard and to document and express what she felt and thought. Sometimes at five or six in the morning, before work (and sometimes Saturdays), she ran away from home to work. She called her creative urge her “monster” and was clear that she must keep her relationship with “him” away from her family. She named all of her retreat places “Selah” a word from the Hebrew Bible that has many meanings, one of which is an instruction on how to read the text, approximately: “stop and listen.” The earliest Selahs were caves and shacks, but as Ashton-Warner became a well-known author and with her husband built a beautiful house, that Selah was a separate, comfortable study room.

The relationship between Ashton-Warner and her husband was much more egalitarian than was the norm in New Zealand in the 1930s to 1950s. Henderson took care of the children for hours several times a week to allow Ashton-Warner to work in her Selah. His children remember him as the more available, generative parent and her as someone who needed time and space away from them to deal with her urgent need to use art to represent her experience.

Early educators will find some of Ashton-Warner’s books more helpful than others. *Bell Call*, *Incense to Idols*, and *Three* have little or no bearing on education in this century, but *Teacher* and *Spinster* do. Their publication came in a strange order: First Ashton-Warner tried to get her writing about teaching published, but publishers rejected it. Then Ashton-Warner rewrote her teaching book, adding some love interest and telling it as a novel, *Spinster*. *Spinster* was a best-seller, reviewed on the front page of the Sunday Book Review section of *The New York Times*. Once *Spinster* made her famous, Ashton-Warner could go back to what she first intended and publish *Teacher*. The two books overlap about one third of their contents. She became a prize author to the American editor

Robert Gottlieb. Her American book *Spearpoint*, like all the books she wrote after her husband's death in 1969, has a depressed tone and complains about the undisciplined children she taught in Aspen, Colorado. Her autobiography, *I Passed This Way*, unpacked her many journals into a long story of life and work. Her book *Myself*, which tells of her most productive period of teaching, has strong appeal to young adult readers. It tells of her supporting herself, believing in her work, going against the odds, and accomplishing what she set out to do. It is, arguably, the most feminist of her writings. *Greenstone*, the novel based on her childhood, features a father who tells stories to his children and Maori and White children who live on either side of the Whanganui River.

Her life sets an example, giving teachers an idea of the ways one can develop a perspective that leads to inventing more appropriate teaching methods and fuller self-expression both for the children and for the teacher. Ashton-Warner stands in history as a difficult, thoughtful woman who cared passionately about getting teaching right and was analytical, passionate, and persistent in her approach to children's development and her own.

COACHING

Coaching in early childhood education can take place in a variety of settings and can occur throughout the course of a person's career in this field. However, the concept and purpose of coaching remains relatively the same across settings and professional life stages. Coaching can be defined as a voluntary, interactive process between a coach and a learner who both engage in observation, reflection, and learning to support the learner's acquisition of knowledge, skills, or dispositions. This entry provides information about the essential elements of coaching in early childhood, including components to successful coaching relationships, stages of coaching, various structures for coaching, and the benefits of engaging in coaching relationships.

Overview

Increasingly, coaching in early childhood education is becoming a much sought after approach to professional development since coaching can be a benefit for both the coach and the learner. The coach engages with the learner and shares his or her knowledge and experiences to support the learner in meeting their stated goals. Assisting colleagues with improving their skills provides coaches with a sense of appreciation for the knowledge they have acquired over their years in the field and has been shown to serve as a retention tool. Early childhood educators who serve as coaches view their professional experiences as more valued and valuable when they are able to share their knowledge with others. Thus, coaching can have benefits

for the coach, the learner, the children and families in the care of the learner, the learner's workplace, and the profession as a whole.

The Coaching Relationship

Engaging in a thoughtful, honest, meaningful, and professional coaching relationship can be a career changing experience for both the coach and the learner. Considerations such as time commitments, goodness of fit with personalities, and knowledge and skills appropriate to the goals of the learner are just a few of the concerns that must be attended to in order to support an effective coaching relationship in early childhood. Both the coach and the learner must have appropriate, realistic, and similar goals in order for the relationship to have the desired outcomes.

Establishing and prioritizing goals are a critical component that the learner needs to begin before seeking out an appropriate coach. A coach should have the skills and knowledge to help support the learner in attaining his or her goals. The coach should also have the personality and behavioral traits to communicate effectively with the learner. If the coach and learner cannot listen to and hear each other, the benefits of the coaching relationship will be limited and neither person will receive the full benefits of the experience.

Stages of Coaching

The first stage of a coaching relationship occurs either when the learner seeks out a coach or a coach invites a learner into the process. This stage develops from a process of observation by either the learner or the coach and leads to an awareness of a skill or knowledge base that has a gap or is missing completely. Identifying a need is a critical step in determining an appropriate coach and in establishing specific goals for addressing needs. Learners need to be receptive to the coaching process and coaches need to be willing and able to share their experiences with the learner. Developing a plan to reach the desired goals and outcomes occurs during this stage and should be a joint conversation between the learner and the coach. This

collaborative approach has been the focus of much research in the field and is viewed as the most likely approach to ensure successful attainment of the learner's goals.

The second stage of a coaching relationship is for the coach to gather data on the learner's current knowledge and skills so that a clear understanding of where the learner is with his or her skills and knowledge can be assessed. Only with this knowledge can a viable plan of action be developed specifically to address the identified needs of the learner. The coach may elect to conduct observations of the learner, conduct interviews with the learner and the people impacted by the goals the learner and coach have established, and provide opportunities for the learner to observe the coach in similar situations. The learner should be integrating new knowledge during this stage of the coaching process.

Reflection and evaluation are the final two stages recommended for successful coaching experiences. In these stages, the collaborative relationship with the learner and the coach shifts to a period of summarization and analysis of the observations and actions that have occurred during the earlier stages of the relationship. A thorough review of the strategies that were effective, areas that may still need further development, and the creation of a continuation plan is discussed. Additionally, the effectiveness of the coaching relationship is evaluated.

The Benefits of Engaging in Coaching Relationships

Coaching relationships provide experiences that can benefit coaches, learners, children and their families, as well as the people the learner interacts with at the work environment. When learners gain knowledge and skills that are specific to their concerns they are more likely to implement the strategies and information gained through the coaching experience. Coaching provides learners with the confidence to practice their new skills and to make a positive difference in the lives of the children in their care. Learners also increase their understanding of the value of observation and

reflection and can use these activities throughout their career.

Coaches and colleagues can benefit from successful coaching relationships by sharing their experiences and knowledge with learners. Offering their experiences provides a sense of validation and affirmation for the coaches. In addition, coaches often report learning from the learners and from the coaching process. In essence, serving as a coach can be considered a professional development activity for the coach as well.

The children and families that the learner interacts with will benefit from the new knowledge and skills that the learner acquired during the coaching process. The learner may have elected to focus on increasing communication skills, child development knowledge, curriculum development for the classroom, language acquisition activities for young children, or alternative therapies for the children in his or her classroom. The learner can then apply these new skills and strategies to directly affect the children and families in their care.

As learners increase their awareness of best practices in the field of early childhood, they may gain the self-assurance to serve as a coach in the future—continuing the coaching cycle to assist all early childhood educators to provide the best care for young children and their families.

COGNITIVE DEVELOPMENTAL THEORY

Jean Piaget's (1896–1980) *cognitive developmental theory* offers descriptions and explanations of children's mental and social-emotional growth from infancy to adolescence. Piaget developed creative methods to assess children's thinking in content areas that are relevant for early education, including language and symbol use, moral judgment, mathematics, logical reasoning, and spatial relationships. Cognitive developmental theory is the basis for *constructivist* approaches to early education that provides a framework for determining the aims of early education and teachers' roles in creating inclusive and effective learning environments for young children.

Cognitive Development in Infancy: Sensory-Motor Intelligence

Cognitive developmental theory mapped the origins and the gradual progression of goal-directed, intentional behaviors from birth to about 18 months of age. These achievements are foundational for subsequent growth of intelligence during childhood. These adaptive, instrumental infant behaviors reflect *sensory-motor* intelligence since the underlying framework for behaving is action-based, not symbolic.

Stages of Sensory-Motor Development

Stage 1: Reflexes

At birth, infants show spontaneous global activities and several specific reflexes such as sucking and grasping. The newborn's first intelligent adaptations consist of differentiating these reflexes from spontaneous global activities. Sucking, for example, becomes more systematic just a few days after birth.

Stage 2: Habits

The repetition of reflexive behaviors such as sucking leads to behaviors that are no longer reflexive but reflect a greater degree of instrumentality on the part of the infant. For example, the infant might accidentally place a finger in her mouth

and begin to suck vigorously. Whether stemming from the spontaneous activity of the infant, or from repetitions in events initiated by caregivers, habits are commonplace.

Stage 3: Primary Circular Reactions

At around 4 to 5 months of age, most infants are able to coordinate vision and grasping. This leads to behavioral patterns called *primary circular reactions* that mark a transition from habits to deliberate means-end, problem-solving behaviors. In a primary circular reaction, interesting or pleasing outcomes that result from actions cause the infant to repeat the action in order to bring about the interesting outcome once again. Although they represent intellectual advancement beyond habits, end results are still not differentiated from the means of attainment in primary circular reactions.

Stage 4: Simple Practical Acts of Intelligence

Around 6 to 9 months of age, infants form behavioral intentions prior to acting and are able to use different actions already in their behavioral repertoires to attain objectives. These practical acts of intelligence often consist of coordinating various means with intended outcomes. Infants understand that objects that they have just seen continue to exist even if they are out of sight. They will search for the object when it is covered under a blanket, for example. However, the infant's understanding of *object permanence* is limited at this stage. Infants will continue to search for an object under the first cover that revealed the object rather than track movements to successive covers.

Stage 5: Sophisticated Practical Acts of Intelligence

Toward the end of the first year, infants show increasing sophistication in attaining objectives. For example, if a desired object is placed on the far end of a blanket out of reach, the infant will pull on a proximate corner of the blanket to bring the object near. The infant is now capable of developing new means to achieve desired ends. At this

stage, infants will search for an object that has been successfully hidden in two different locations but will discontinue object searches when covers, nesting, and hiding occurs out of the infant's view.

Stage 6: Dawn of Representational Intelligence

Having established a firm base of practical or sensory-motor intelligence in stages 1 to 5, a qualitatively new feature appears between 12 to 18 months of age. The infant is able to mentally derive new means to achieve desired ends prior to acting. The infant can devise a novel behavioral sequence to achieve a goal without any trial-and-error attempts. This reflects a milestone in the growth of intelligence. Infants now understand that objects exist independently of the self and continue to search for an object that has been hidden within multiple, nested covers.

Imitation and Play in Infancy

Early forms of imitation and play are evident in infancy starting around stage 2. In imitation, the baby attempts to reproduce behaviors performed by others. At first, the infant is only capable of doing so when the person imitates a behavior just performed by the infant. Subsequently, infants will attempt to reproduce adult-initiated behaviors, even novel ones. In the earliest form of play, the infant repeats actions already acquired without any social prompting. Imitation and play are indicators of the child's cognitive achievements.

Cognitive Development in Early Childhood

Cognitive developmental theory maintains that the sensory-motor achievements of infancy are reconstructed at an interior, cognitive level from early to late childhood. For example, between ages 1 and 2 years, babies are able to navigate familiar environments with creeping, crawling, and walking. They show a practical understanding of left-right and near-far relations; they can navigate around detours, and so forth. This practical understanding of spatial

relations is not immediately registered in children's mental representations of spatial relations. For example, children's drawings of physical environments do not successfully represent left-right and near-far relationships until middle to late childhood. In general, children's understanding and representations of what they know how to do with their bodies and senses take several years to perfect and become accurate. Practical success precedes representational understanding in child development.

Preoperational Thinking

Between the ages of 2 and 6 years, children show growth in their understanding of the physical and social worlds, in their ability to reason logically, and in their use and mastery of speech, language, and other symbolic instruments such as symbolic play, mental imagery, and drawing. At the beginning of this period, children's symbol use, thinking, and problem solving are highly subjective and tightly bound by prior experiences and contexts. Although capable of using symbols to represent absent realities, young children have difficulty generating ideas and possibilities that go beyond their everyday life experiences. Imitation of others, first evident in infancy, is a ubiquitous aspect of early childhood. In the context of games, children ages 4 to 6 years understand that games have rules, and they view the rules as immutable and not open to modification. This belief is held even though children have difficulty adhering to the rules. In the world of preschool children more than one child can "win" a game.

Although capable of using thoughts to plan and organize problem-solving approaches before acting, young children's ideas and judgments are subjective, imprecise, and qualitative in nature, especially as compared with those of older children and adolescents. For example, when asked to reason about the impact of a transformation on an initial state, young children struggle to coordinate {initial state}-transformation-{end state} relationships. A 4-year-old child might judge, for example, that the quantity of liquid has increased when a

glass of juice is poured from a shorter, stouter glass, into a taller, thinner glass. The child reasons on the basis of the end-state and only one dimension (height) rather than considering two dimensions, equating "taller" with "more quantity." The ability to mentally coordinate states of reality with transformations involves *operational thinking*. An operation is an internal, thinking act that has the property of *reversibility*. Young children's operational thinking is not fully formed—lacking the property of reversibility—and is called *preoperational*. Cognitive developmental theory maps out the progression from sensory-motor to preoperational to operational thinking in many content areas such as understanding of logical reasoning, physical quantity, causality, and time and space.

Imitation and Play in Early Childhood

Growth in operational thinking underlies growth in symbol use according to cognitive developmental theory. The theory was the first to point out that children's initial facilities with language, mental imagery, symbolic play, delayed imitation, and drawing become evident at the same point in cognitive development. Subsequent growth in use of these symbol systems both stems from and supports growth in operational intelligence.

Even with the most permissive parenting styles, young children have many constraints on their behaviors for reasons of health, safety, and socialization. *Symbolic play* allows young children to satisfy affective needs via self-expressions that are not governed by adults and older children. In symbolic play, acting either alone or with a playmate, children use speech, gestures, and objects to re-create and represent previously experienced realities. These representations both exercise growing intelligence and allow the child to "work through" experiences that were emotionally laden. Imitations of others' behaviors witnessed in the past are typically embedded in symbolic play sequences. Young children enjoy activities that involve repetition and attention to the external environment, such as singing songs, coloring scenes, listening to stories, and so forth. Like symbolic play, these and other

imitation-based activities are an important and necessary aspect of cognitive development.

Concrete Operational Thinking

Between the ages of 6 and 8 years, many of the cognitive achievements of early childhood continue to develop. Children's thinking and reasoning about people and real (not hypothetical) objects become more systematic, flexible, and reversible. In middle childhood, thinking advances from preoperational to *concrete operational* in some but not all domains. For example, children are able to reason correctly about physical quantities and certain numerical relationships, but they struggle with complex properties such as understanding volume and proportional relationships. Thus, in middle childhood one can observe a mixture of preoperational and concrete operational thinking depending on the domain or content area in question. In addition, children's reasoning about objects is more advanced than reasoning about verbal propositions.

By middle childhood, most youngsters have had extensive experiences with age peers. Cognitive developmental theory maintains that peer experiences are an important factor in both the cognitive and social-moral growth of children. In interactions with adults there is always an element of *unilateral respect* since the adult has final say in what the child can and cannot do. In peer relationships, the possibility for *mutual respect* is at hand since children have to negotiate interactional rules without adult supervision. For example, children might take turns deciding who determines the next joint activity. Although symbolic play is still enacted in middle childhood, games with rules are discovered and usually found to be enjoyable. During this age period, children begin to understand that game rules are "social contracts."

Explaining Cognitive Development

Cognitive developmental theory maintains that the most important source of intellectual growth and advancement lies within each child. The theory postulates (a) children are born with tendencies to

be active agents in the physical and social worlds; (b) children have a biologically based inner ability to self-regulate (called *equilibration*); and (c) self-regulation coordinates the contributions of other key factors in intellectual development, including maturation of the nervous and endocrine systems, experiences with physical objects, and social interactions, including teaching, transmissions, and socialization.

Meaning Making

Cognitive developmental theory assumes that all children *make meaning* via the application of cognitive systems that are formed soon after birth. Parents and teachers can infer the nature of the infant's or child's cognitive system by observing regularities in everyday behaviors. In addition, cognitive developmental theory has created specialized methods to assess children's thinking and problem solving that can be used to supplement everyday observations. For example, there are ways to test whether an infant has developed object permanence; *clinical interviews* test for understanding of reversibility and operational intelligence. Meaning making is a ubiquitous aspect of life in early childhood. Intellectual curiosity reflects children's need and desire to apply their previously developed cognitive frameworks to present situations and contexts. Meaning making entails a relationship between the child's cognitive system and a given context of application.

Assimilation and Accommodation

Cognitive systems make meaning via processes of *assimilation* and *accommodation*. Assimilation is an inner-directed process such that an object, event, or problem is incorporated into a cognitive system. Accommodation is an outward-directed process such that the cognitive system takes account of the specific features of the object, event, or problem in question.

Assimilation and accommodation are simultaneous processes that occur in every act of knowing. The processes of assimilation and accommodation always result in a degree of success or understanding depending on how well equipped the cognitive

system is able to handle the given context. Some forms of meaning making, such as imitation, rely more heavily on accommodation. In imitation, the child seeks to copy something rather than interpret it. Other forms of meaning making, such as symbolic play, rely more heavily on assimilation. In symbolic play, the child is not concerned with a faithful reproduction of an object or event but instead seeks to create his or her own meaning or interpretation. Both imitation and symbolic play are reflections of the child's inner cognitive system. However, intellectual advancement is more likely to occur when assimilation and accommodation are more equally weighted or balanced in a given context of occurrence.

Growth in Meaning Making

Meaning making in a given context is a necessary but not sufficient first step for growth or advancement in the cognitive systems. The default tendency following application of cognitive systems is that they remain unchanged—despite how successful or unsuccessful they might have been. Indeed, young children enjoy repetition and resist making changes to familiar routines. Experiences of success or failure in attaining a goal—whether they occur in private or social (including classroom) contexts—may or may not lead to self-regulatory efforts to modify the cognitive systems. The system needs to experience *perturbations* in order to modify itself. Although social processes such as verbal feedback or scaffolding in problem solving play a role in the growth of cognitive systems, they are not sufficient to ensure lasting change and growth. The self-regulatory process of equilibration orchestrates or coordinates the overall functioning and growth of cognitive systems.

Implications for Early Childhood Education

Children Are Intellectually Curious

Cognitive developmental theory teaches us that children are intellectually curious. The source of this curiosity lies within children as part of their

evolutionary birthrights. If properly structured, early childhood classrooms do not have to be overly concerned with children's attention spans or with providing extrinsic rewards for engagement with curriculum tasks. Young children are eager to “exercise” their cognitive systems.

Individual Differences in Speed of Development

Although all children progress through the stages of cognitive development, the speed of attainment varies considerably both within a particular cultural or disability context and across contexts. For example, one child might attain concrete operational understanding of a given phenomenon at age 6, whereas another child might attain the same level of understanding at age 8. Cognitive developmental theory emphasizes the fact that these two children progress through the same levels of understanding rather than the fact that one child is “ahead” of the other child in terms of age of attainment. The speed of academic mastery is not emphasized in cognitive developmental theory.

Probe for Understanding

Early childhood educators need a firm grasp on what their students know and can do. By probing for understanding using clinical interview methods, early childhood educators can obtain a more complete picture of what students know. For example, a child might answer a question correctly, but his or her reasoning might be shallow or superficial. The child might be simply repeating a parent's or teacher's answer without understanding why that answer is correct. Another child might answer incorrectly but have good reasons for his or her answer and be close to devising the correct answer. A teacher whose assessments stop at right or wrong answers might misclassify children's overall levels of understanding. As time permits, it is best to probe for why children reason and conclude as they do. The mental processes and strategies that lie behind children's “final answers” are extremely instructive for early childhood educators.

Teachers' Roles

Cognitive developmental theory has a clear vision for teachers' roles in creating effective early childhood classroom contexts. Children cannot be left to their own devices with the hope that they will "discover" curriculum objectives with minimal instruction or guidance. Such an approach runs the risk that children will respond to the curriculum in individualistic, playful manners and not make adequate progress in content mastery. On the other hand, teacher-dominated instructional approaches with rigid schedules for completion of curriculum tasks run the risk of forcing students to imitate or copy what the teacher wants or what other children do and say.

A middle-ground approach championed by cognitive developmental theory is the teacher as *mentor*. Based on solid mastery of the curriculum content and the nature of children's development, teachers can tailor instructional approaches to individual children's needs. They do so by posing developmentally appropriate curriculum tasks and monitoring children's understanding as students engage with the materials. Teachers play a critical role in constructivist classrooms.

Finally, teachers need to show that they respect children's efforts to learn and master curriculum content. One way to do so is to model intellectual inquiry. Teachers need to show that they are learners, too. This sets a context in which respect for each student's efforts at learning becomes normative. The context in which children learn—classrooms with mutual respect for others' opinions and approaches—is critically important in the early childhood classroom. How children learn in classrooms is as important as both "what" and "how much" they learn.

COHABITATION

Cohabitation, or living together in an intimate sexual relationship outside of marriage, has become commonplace in the United States. Just a few decades ago, marriage was the foundation for intimate coresidential partnership for heterosexual couples. Now roughly 70% of marriages begin as cohabiting relationships, and nearly 70% of women ages 30 to 34 have cohabited at some point. In addition, cohabitation has become the main source of nonmarital childbearing. According to analyses conducted by the National Center for Family and Marriage Research and reported in 2015, about 43% of children are born outside marriage. Of these, nearly 60% are born to cohabiting couples. Thus, the majority of nonmarital births are not to single women but to cohabiting couples.

Children are thus involved in cohabitation. Social and behavioral scientists are studying the impact and meaning of cohabitation in general as well as its

implications for children. This entry reviews scholarship on the latter. All numbers reported here are based on data from the U.S. Census Bureau or on analyses of high-quality, nationally representative survey data.

Children in Cohabiting Unions

There are two ways that children experience this family type. The first is by being born to cohabiting parents; the fraction of births to cohabiting parents has increased substantially from 6% in the 1980s compared to nearly 25% for births occurring between 2009 and 2013, according to the National Center for Family and Marriage Research. The other way is when the primary parent, typically the mother, begins to live with a boyfriend. This is often called a “cohabiting stepfamily.”

The U.S. Bureau of the Census reports that 40% of opposite-sex cohabiting households include children. The percentages are higher for specific age ranges. In cohabiting households in which the female partner is 30 to 34 years old, the percentage with children is 56%; for 35- to 39-year-olds, the percentage is 63%.

There are also differences by race and ethnicity. For Whites and Asians, the percentage of cohabitations in which children are present is 37%. Among Blacks and Hispanics, the corresponding percentages are 49% and 57%, respectively. In addition, parents' education, often used as a rough proxy for social class, is associated with differentials in whether children are present in cohabiting relationships. The most highly educated, those with a bachelor's degree or more, are least likely to have children in the household (19%), whereas those who did not finish high school are most likely (57%).

Correspondingly, childbearing while cohabiting is not unusual, but it is least common for the most highly educated. In other words, there is an inverse correlation between social class and the likelihood of children being born outside marriage. Stated another way, those who are economically disadvantaged are more likely to bear children outside of marriage, including while cohabiting. Still, although highly educated women are much less likely to have a nonmarital birth overall than less educated

women, when they do, they are more likely to do so while cohabiting than as a single woman. For instance, 44% of women without a high school degree who have a nonmarital birth are living with the biological father. The percentage for women with at least some college education is 60%.

These numbers underscore a key theme in the scholarship on cohabitation: Cohabitation tends to be a step to marriage among the most economically advantaged (i.e., cohabit, marry, and then have children). In contrast, although economically disadvantaged couples desire marriage as much as their more advantaged counterparts, they are less likely to marry. Studies suggest they do not feel ready to marry unless and until they attain a sense of economic stability and a positive economic trajectory.

Cohabitation and Child Well-Being

That cohabitation is so prevalent in the lives of children today has sparked debate among scholars and policy makers alike concerning the implications of parental cohabitation for child well-being. Just as numerous studies in the 1980s and 1990s explored the implications of divorce for children, family scholars are now examining the ramifications of cohabitation for children.

Research suggests that a major ramification concerns family instability. This matters because children typically fare best in stable family structures; numerous studies have documented that family instability tends to have negative consequences for children.

Cohabiting relationships in general are short. Most dissolve or become marriages within a few years of the start of the cohabitation, and they are much more likely to dissolve than marriages. Indeed, studies show that children born to cohabiting couples are more likely to see their parents' relationship dissolve than children born to married parents. Approximately 15% of children born to cohabiting couples experience the end of their parents' union by age 1, half by age 5, and two thirds by age 10. Instability is much lower for children born to married parents. Only 4% and 15% experience their parents' separation by ages 1 and 5, respectively, and 28% by age 10.

The upshot of instability is its connection to child well-being, a major focus of research on cohabitation. In general, studies indicate that parental cohabitation negatively affects child well-being across numerous outcomes, especially in comparison to children raised in married-couple families. Although many children fare well, parental cohabitation has been linked to earlier sexual initiation and greater odds of teen pregnancy for girls, poorer educational outcomes, and behavior problems.

Is it cohabitation itself that causes poorer outcomes? Most scholars would answer “not necessarily.” Children experiencing parental cohabitation are typically disadvantaged in other ways relevant to well-being compared to children raised in married-couple families. Economic status is one of those ways. According to 2014 data from the U.S. Census, nearly 50% of children in cohabiting families are living in poverty compared to 11% of children in married-couple households. Thus, the idea is that cohabitation itself is not an issue but is more commonly the site for childbearing and childrearing among less advantaged groups.

Indeed, studies indicate that differences in family stability and economic well-being do partially explain why children are worse off in cohabiting versus married households. On average, cohabiting families are poorer and more fragile.

Conclusion

Recent decades have seen dramatic increases in the number of couples who cohabit, and many of these couples have children. Research suggests that children experiencing parental cohabitation face some obstacles. Two primary ones are family instability and a lack of economic resources. To the extent that children in cohabiting families could live in as stable living arrangements as children with married parents, research would likely show fewer differences in well-being between these groups of children. The same is true for economic resources; if income could be equalized across family structures, we would arguably see a narrowing of the family structure gap in child well-being.

COLLABORATIVE FOR ACADEMIC, SOCIAL, AND EMOTIONAL LEARNING

The Collaborative for Academic, Social, and Emotional Learning (CASEL) is the premier organization advancing research, school-based programming, and public policy focused on the development of children’s social and emotional competence. Founded in 1994 and based in Chicago, Illinois, CASEL aims to integrate evidence-based social and emotional learning (SEL) into education settings from preschool through high school. This entry summarizes CASEL’s orienting definition of SEL; some key accomplishments; and plans for future developments in SEL research, policy, and practice.

Defining Social and Emotional Learning

CASEL has identified five interrelated sets of cognitive, affective, and behavioral competencies that are critical to helping young people succeed in school and life. Notably, these competencies are not learned in isolation; instead social and emotional learning, the process of acquiring and applying the skills defined in the following list, is rooted in a child's social relationships with adults and peers. The five core competencies, as defined by CASEL, are as follows:

1. *Self-awareness*: The ability to accurately recognize one's emotions and thoughts and their influence on behavior
2. *Self-management*: The ability to regulate one's emotions, thoughts, and behaviors and to set and work toward personal and academic goals
3. *Social awareness*: The ability to take the perspective of and empathize with others from diverse backgrounds and cultures and to recognize family, school, and community resources and supports
4. *Relationship skills*: The ability to establish and maintain healthy and rewarding relationships with diverse individuals and groups through communicating clearly, listening actively, cooperating, and negotiating conflict constructively
5. *Responsible decision making*: The ability to make constructive and respectful choices about personal and social interactions based on consideration of ethical standards, the realistic evaluation of consequences of various actions, and the well-being of self and others

CASEL views integrated school-based SEL programming as the most promising educational reform to promote the academic success and well-being of children and youth. Successful SEL programs not only aim to foster the core competencies defined earlier but also promote positive student attitudes about self, others, and school, and support the creation of caring classroom environments and school

cultures where children and adults feel a sense of safety and belonging. Research into the effectiveness of SEL programs shows that they lead to better school adjustment and academic performance for students. Schools that implement such programs have seen beneficial changes in their students such as gains in positive social behavior and peer relationships, fewer conduct problems, reduced aggression and reduced drug use, less emotional distress, and better grades and test scores.

However, CASEL is keenly aware that the implementation of SEL programs necessitates careful planning and integrated support at all levels of the education system. In its theory of action for systemic SEL, CASEL argues that SEL programs are most powerful when used as a unifying framework to coordinate efforts to promote positive school culture and climate, student-centered learning, youth development, health and mental health, character, service-learning, and citizenship. Throughout its research and publications, CASEL emphasizes that SEL efforts are most beneficial when they

- include theoretically sound, research-based classroom instructional practices that promote children's social-emotional competence and character;
- encourage student engagement in positive activities in and out of the classroom;
- are implemented by educators who receive continuing professional development and administrative support at the district central office and school levels;
- encourage broad family and community involvement in program planning, implementation, and evaluation; and
- are evaluated regularly to monitor implementation, assess student outcomes, and improve future efforts.

Key Projects and Initiatives

CASEL acts as a clearinghouse for cutting-edge research into SEL; translating scientific knowledge into effective district, school, and classroom practices; and disseminating information about scientifically based SEL approaches. CASEL works to

enhance the professional preparation and learning of educators so they have the knowledge and tools to implement high-quality SEL instruction. Furthermore, CASEL networks and collaborates with educators, scientists, policy makers, community leaders, and child advocates to establish federal, state, and local education policies that foster high-quality implementation of SEL practice. Currently, CASEL is collaborating with top scientists and practitioners to advance SEL research, practice, and policy in an ambitious effort to take SEL to scale nationwide. Although CASEL's work encompasses SEL from preschool to high school, this entry focuses primarily on early childhood programming across education standards, curriculum, assessment, and implementation in preschool and elementary settings.

Disseminating information About SEL Programs to Early Childhood Educators. In an effort to further support the adoption and implementation of SEL programs, CASEL has developed guidelines to help educators identify appropriate evidence-based SEL programming for their students. CASEL staff review and judge nationally available curricula for their effectiveness and disseminate information about the best scientifically based programs available to educators. The *CASEL Guide: Effective Social and Emotional Learning—Preschool and Elementary School Edition* was published in 2013.

The *CASEL Guides* provide a systematic framework for evaluating the quality of classroom-based social and emotional learning programs. They then apply this framework to identify well-designed, evidence-based SEL programs with potential for broad dissemination to schools across the United States. The programs that CASEL recommends must meet three criteria: (1) be a well-designed classroom or school program that systematically promotes students' social and emotional competence, provides opportunities for practice, and offers multiyear programming; (2) deliver high-quality initial training and ongoing technical assistance to ensure sound implementation; and (3) be research-based, with at least one carefully conducted evaluation that documents positive

impacts on student behavior and/or academic performance. Through the *Guides*, CASEL also shares best-practice guidelines for district and school teams, explaining how to select and implement SEL programs and recommending future priorities to advance SEL research, practice, and policy.

Supporting Federal and State SEL Policies. In part because of CASEL's earlier work, there has been significant progress in the past decade establishing SEL as a component of education policy. CASEL regularly collaborates with congressional and U.S. Department of Education staff, recommending specific language for legislation. CASEL worked to promote the Academic, Social, and Emotional Learning Act of 2013 (H.R. 1875), which would have allowed flexible use of federal funds to train teachers and administrators to implement SEL programming.

Early in 2015 CASEL worked to support the introduction of two SEL-related bills to Congress: H.R. 497, the Supporting Social and Emotional Learning Act, to require training for teachers in SEL programming, and H.R. 850, the Academic, Social, and Emotional Learning Act, to support evidence-based SEL programming. Additionally, CASEL has worked to support a companion bill introduced to the Senate (S. 897) in 2015 to support the use of evidence-based SEL programming.

Ultimately, through its policy work, CASEL aims to add language to the Elementary and Secondary Education Act and Department of Education competitive grants that would promote SEL adoption, implementation, and evaluation.

CASEL has also worked extensively at the state level, advocating for and informing the development of state standards of SEL. CASEL worked closely with the Illinois State Board of Education when, in 2004, Illinois became the first state to establish preschool to high school SEL standards as part of its student learning standards. In an effort to elucidate the status of SEL standards nationwide, CASEL initiated an ongoing scan of state policies and standards related to social and emotional learning in 2010. The purpose of CASEL's state scan is to assess current SEL standards across

the country. The state scan project called attention to the fact that although all 50 states currently have free-standing SEL standards for preschool children, there are only a handful of trailblazing states implementing SEL standards from prekindergarten through 12th grade.

In 2013, CASEL published a brief report based on these state scan efforts calling for alignment of preschool and K–12 state standards for SEL. This brief report presents overviews of SEL competencies and state standards and includes examples of aligned SEL standards in two states, Illinois and Pennsylvania, which have been leaders in the field.

Evaluating SEL Assessment. The inclusion of SEL in state standards of learning has increased attention to outcomes at the classroom level. Thus, more than ever, valid and reliable research-based social-emotional assessment tools are necessary to support program evaluation and to assist educators in maximizing the success of specific children. High-quality direct assessment of SEL in early childhood, in particular, is both developmentally appropriate and more pressing given that SEL programs and policies at this age may ameliorate some of the effects of poverty on school readiness.

Recognizing this need, CASEL convened a work group in 2010 to create a compendium of SEL-associated assessments for preschool through elementary school. Through the compendium, CASEL aims to enable researchers and other interested users to track young children's SEL across the five core competencies defined earlier. In addition to child assessments, the compendium also includes assessments of the classroom contexts in which SEL takes place, including ratings of classroom management, instructional support, healthy relationships in schools, social and emotional skills instruction, and opportunities for social and emotional skill applications. Finally, assessments of SEL-related academic outcomes were also included (e.g., attitudes toward learning, cooperative participation in the classroom). For each area of assessment, the extant tools considered useful were organized by age and type (e.g., teacher report, observational or direct assessment). Summaries are

provided for each assessment tool's psychometric properties and administration procedures. The compendium is available on the CASEL website for public use.

Collaborating With School Districts Toward Systemic SEL. In 2011 CASEL launched its national Collaborative Districts Initiative (CDI), aimed at supporting districts' capacities to promote SEL for all students. Through the CDI, CASEL is partnering with eight large urban school districts to improve student outcomes by building district capacities to support SEL. The CDI is designed to achieve two complementary goals:

1. To develop districts' capacities to plan, implement, and monitor systemic changes that will impact schools and classrooms in ways that enhance students' social-emotional development and academic performance
2. To document lessons learned that can inform future efforts to support systemic SEL implementation in districts across the country

Creating and Evaluating Resources for Schools. One of the resources being utilized in the ongoing CDI is the CASEL *SchoolKit*. The *SchoolKit* is a school-wide support intervention that is based on strong theory and empirical research on implementation. It is innovative because it provides strategies for building schools' capacity to effectively implement and sustain evidence-based SEL programs, taking into account individual and organizational factors that influence the implementation and that directly influence student outcomes.

Beginning in 2014, with support from the U.S. Department of Education's Investing in Innovation (i3) Funds and NoVo Foundation, CASEL launched a study to assess the differential impact of free-standing classroom-based SEL versus classroom-based SEL that has been fully integrated school-wide. The study will determine if CASEL's school-wide approach to supporting SEL (via the *SchoolKit*) has the power to transform low-performing schools and improve their students' academic performance. Implemented in 28 Chicago

Public Schools, this is the most ambitious application and study of systemic SEL.

Conclusion

For more than 2 decades, CASEL has led the way in the promotion of evidence-based social and emotional learning from preschool to high school. Through research, practice, and policy, CASEL collaborates to ensure all students become knowledgeable, responsible, caring, and contributing members of society. In the coming decade, as national attention turns toward the quality of early childhood education, CASEL will continue to call for the promotion of SEL programs and policies for our youngest learners while emphasizing the importance of grounding this work in a strong research base.

COMER SCHOOLS

The Yale Child Study Center School Development Program (SDP) is commonly called the Comer SDP after founder James P. Comer. It grew out of collaboration between the New Haven Public Schools and the Yale Child Study Center. It was initiated in two pilot elementary schools in New Haven, Connecticut, in 1968. The intervention research model created has been used in about 1,000 schools nationally and internationally. It is probably the longest running school intervention approach in the country and is the first to demonstrate and codify a successful school improvement approach among largely less privileged African American students. It has also been effective with mainstream children from all racial and socioeconomic groups.

In 1969 the two pilot schools were 32nd and 33rd in achievement among 33 schools; had the worst student and staff attendance; and had continuous, sometimes serious behavior problems. One pilot was closed and replaced with a similar school. In 1983, with no significant change in the student or community populations, the two schools were 3rd and 4th in academic achievement, were best in student and staff attendance in the city, and had no serious behavior problems.

The child development centered process change model that grew out of the pilot work was successfully field tested in nine schools. SDP staff learned that buy-in of change was more likely when a local person or group facilitated the change process. SDP staff created a trainer or (facilitator) program that made this possible. This made widespread dissemination possible.

This entry discusses the origins of the SDP, including experiences in Comer's background that led to his interest in behavior and a holistic approach to education. It then discusses the development of the SDP model and how it was disseminated to other schools. Finally, it discusses the implications of the program for schools and for education policy.

Concept Origins and Insights

Comer had planned to become a general practitioner of medicine, but while doing an internship in his hometown of East Chicago, Indiana, he noted that three classmates dating back to kindergarten were on a downhill course in life. Eventually, one would have a life-long struggle with mental illness, another died early from alcoholism, and the third served a long prison term. These conditions adversely affected their children, the community, and the society. Meanwhile, Comer and his siblings collectively earned 13 college degrees, had rewarding family and professional lives, and contributed to community service.

Comer and his classmates had attended the same racially integrated school with classmates from across the full socioeconomic spectrum. Their parents had similar backgrounds: poorly educated (Comer's mother was nearly illiterate) African American immigrants from the rural South who worked as domestics, steel mill laborers, and custodians. All the parents appeared to be caring, able people. What contributed most to the different outcomes of their children?

Comer determined that the critical differences were his parents' commitment to education for their five children; the ability to promote their personal development with low, but just enough, income to support their family; and participation in a church culture and network that provided the social, psychological, and emotional skills and support necessary for family stability. An important and often overlooked factor was parental access to mainstream social capital.

During the first 12 years of Comer's parents' marriage, before he was born as their first child, his mother worked as a domestic for several of the

most affluent and socially well connected families in their town. This provided opportunities to experience mainstream functioning uncommon to most poor families and children and, later on, jobs that supported their higher education. Their church culture enabled their family to participate in leadership roles that provided a sense of ownership and unquestioned belonging within an institution important to them and respected in the mainstream society. There was considerable overlap between their church-centered community network culture and that of the school. The school is a central mainstream institution. Success in church and school greatly increased their chances for success in life.

Comer began to position himself to better understand human and societal behavior. His journey to understanding began with volunteer work with a group of mothers with small children who were disqualified from welfare support for violation of onerous rules. The ill effects on those parents, the children, schools, and the potential impact on the society led him to thoughts about prevention—through child and adult psychiatry knowledge and skills, particularly child and adolescent development; public health ecology; and a holistic approach to understanding and addressing individual and systemic problems.

Method and Model

Shortly after Comer finished his preparation in child and adolescent psychiatry at the Yale University Child Study Center in 1967, he was asked to lead the center's school program. He and his team decided not to impose an intervention model on the two pilot schools but to participate in the ongoing school process, learn, and, with parents and school staff, co-construct an effective approach to research and intervention. They were guided by what they determined was needed to address the challenges within the school setting. They also decided against trying to racially integrate these largely African American pilot schools. Comer's own success in racially integrated schools while students of similar background and ability were not successful suggested that the students needed vibrant school environments that provided

them with experiences that promoted the kind of development needed to be successful in school more than proximity to White students.

Because of start-up problems one school was immediately highly dysfunctional, the other only slightly better. High hopes among parents, staff, and students turned to initial chaos in one year, followed by modest recovery but continued disappointment, frustration, anger, conflict, difficult behavior, and continued low academic performance. This strengthened the focus of the school program's creators on the power of environment. The idea behind the SDP model is that desired child development and learning are inextricably linked and interactive and can be promoted by mature adults in a reasonably well functioning school environment. The SDP model flowed from the organic creation of structures and processes designed to create these necessary conditions.

Even when school improvement is mandated, it can only take place when key and most influential, and when all participants buy in to an organic—self-change from within—process. SDP gradually moved to this state through the school-based creation of nine nonnegotiable elements that are at the core of its work today. These nine elements consist of three guidelines, three teams, and three operations. All of the elements emerged from problem situations that became apparent during practice; they were not imposed.

Guidelines

The three guidelines are no-fault problem solving, consensus decision making, and collaboration. As the participants work to live by these guidelines, a relationship culture gradually emerges that allows all involved to begin to address the obstacles to success. We identified two underlying problems—first, student experiences that did not prepare them for academic learning and needed behavior; second, educator preparation and practice that did not adequately prepare them to integrate development and academic learning in a way that supported adequate student development and learning and did not join home and community in the task of supporting student development.

Teams

The three teams—school planning and management (SPMT), parents (PT), and school-staff-support (SSST)—enable all the participants in a system of disorganized, inefficient, harmfully redundant moving parts to interact in a synchronous manner.

The SPMT is the engine of the process, is representative of the school stakeholders, and works with the principal, through direct action and delegation, to manage all the operations and activities in the school. The representative stakeholders intentionally involve colleagues. In this way everybody has an avenue for self-expression and problem solving, a sense of ownership of the outcomes and the challenges, and a sense of belonging. Representatives of the PT serve on the SPMT. And the PT carries out its own program, aligned with and in support of the SPMT and designed to address parent needs. The SSST is made up of the helping professionals, such as social workers, nurses, and others, in the school and community. In a coordinated way it addresses the needs of individual students or groups and works with all teams to help the school apply child and adolescent development principles to behavior, teaching, and learning growth opportunities.

Operations

The three operations are the comprehensive school plan, staff development, and assessment and modification. The SPMT establishes the comprehensive school plan and/or the academic and social goals of the school and delegates the work to this operational team or subcommittee. The latter is responsible for the alignment of curriculum, instruction, and assessment matters and for integrating development strategies into the academic program. Staff development is based primarily on what the educator staff identifies as needs through ongoing assessments and ad hoc group-established improvement needs. There can be development efforts for parents, support staff such as bus drivers, and others. Assessment and modification applies primarily to student academic and social

outcomes such as test scores, attendance, and behavior. It is formal and informal, periodic and ongoing.

These elements operating simultaneously and synchronously create a positive and supportive school culture and climate. This makes it possible for students to interact with the more mature adults in the classroom and school, and with the program of the school, and make the kind of attachment and bonding that took place in families and the community before school for many. Most importantly it makes attachment, bonding, support, and guidance available for students who did not experience environments (at home or in the community) that could prepare them for school.

The culture promotes student engagement and motivation. It allows the adults to help them grow along the critical developmental pathways necessary to be successful in school and in life—social-interactive, psychoemotional, moral-ethical, linguistic, cognitive, and executive functioning, and physical, which includes brain circuitry elaboration. Resultant student competence and confidence lead to better academic and behavior outcomes. This allows parents and staff to hold higher expectations and stretch to provide experiences that will provide even greater success.

Dissemination

After field testing indicated the SDP was effective in helping schools improve the academic and social performance of students, in 1990, program staff began to disseminate the model using a trainer of trainer approach that was created in-house. They worked with more than 650 schools in 26 states across the country for more than 3 years. They used three different facilitator approaches—a mental health and social service organization, university-based educators, and Child Study Center staff. The work was extended to several early childhood programs through a partnership and to middle and high schools in a few instances; the latter occurred through national faculty and regional training centers made up of staff trained by the Yale Child Study Center team.

Outcomes and Implications

Evaluations by SDP staff and outside evaluations suggest that two thirds of the schools using the model improved in academic achievement—one third remarkably, another third moderately. One third did not make gains. SDP research shows that academic gains were greatest in schools in which educator buy-in of its developmental approach was highest. In one of the few schools in which a racial comparison was possible, a 40-point achievement gap between Black and White students was closed over a 5-year period, and all students improved. Also, where assessments were done, students who attended SDP schools had higher self-concept and resilience scores than others. Other studies have shown beneficial outcomes for parents and educators.

In a study of 29 best known comprehensive school reform projects (projects designed to improve schools by implementing effective practices in every area) across the United States, the SDP was one of only three to demonstrate that implementation effects are relatively robust and the model can be expected to improve student test scores.

Challenge and Process

The challenge for educational policy makers is to institutionalize integrated development and learning knowledge and skills, and sustain the benefits in a way that improves the American education system on a large scale. Nearly half a century of SDP work with schools, educator preparatory programs, districts, parents, legislators, accreditation programs, and others suggests three prime drivers of underperformance in the American education system(s). First, educator preparation is not based on knowledge of child development and its integration with curriculum, instruction, and assessment. The second is that the critical stakeholders operate in silos, unable to effectively share and integrate potentially useful knowledge and skills. Third, much policy and practice requirements flow from the top-down rather than from the service delivery level and/or bottom-up.

An arrangement is needed that would allow front-line education service delivery needs and findings (the needs of students and families and the educators serving them) to inform district, state and regional, and national practice leaders and policy makers. This would allow high-level policy to better support front-line practice. This kind of change will require a process in which place—a district or community—begins to work with a university that prepares local educators and with a source of developmental knowledge, with state and national education authority involvement, attention, and support. This could reduce the sense of not being adequately prepared, powerlessness, and frustration at the education service delivery level that cause so much dissatisfaction and turnover, conditions that make good teaching and learning almost impossible.

Starting in 2015, the SDP has engaged in an intervention research approach designed to integrate development and learning in educator preparation, reduce silo effects, and promote bottom-up and top-down collaboration.

The goal of this intervention approach is to stop looking for magic bullets—a few rarely gifted educators, innovative new projects, and the like; or working top-down, create a model that can be brought to large scale—and to prepare community, parents, and educators at each school site to create schools and districts in which there are positive relationships; caring, responsible, and predictable adults in the lives of students; a sense of belonging in constructive groups engaged in challenging learning and activities; and an opportunity for students to gain competence and confidence and a sense of direction and life purpose. Academic learning is to take place as a part of a development-centered strategy that prepares students for life and that requires systems to change and work in ways necessary to make this possible.

COMMERCIALISM

Children have long been targets for advertisers, but beginning in the mid-1980s they became subject to an escalation of corporate marketing. This is when the Federal Communications Commission

deregulated children's television, and by act of Congress, the Federal Trade Commission (FTC) lost its ability to regulate most marketing to children. Now, on most issues the FTC can only make recommendations about how products are marketed and not marketed to children; it cannot regulate unless issues of actual bodily harm can be shown to be involved. Changes in government policy occurred with very little public discussion or debate, as discussed by Juliet Schor in *Born to Buy*.

Beyond the ads children see, even more marketing goes into linking the logos from popular children's media to specific products such as food packages, clothing, and daily life items such as lunchboxes featuring Disney princesses and highly successful toy lines such as those based on characters from the Teenage Mutant Ninja Turtles (TMNT) comics, TV series, and movies. On August 25, 2014, www.walmart.com had 736 TMNT products in the categories of toys, movies, video games, clothing, and home furnishings. It is important to note movie or TV show ratings have little to do with age ratings on the products being marketed and advertised in that medium. Although the rating for the 2014 TMNT movie is PG-13, the age recommendations for TMNT toys are as young as 1 year old and there are pajamas for 1-year-olds. Increasingly, even traditional and highly regarded toy lines, such as Legos and Play-Doh, have many media-linked product lines, for instance, TMNT Lego and Disney Princess Play-Doh kits.

This entry discusses the characteristics of children that make them vulnerable to marketing techniques and the relationship between commercialism and children's development, learning, and behavior. It then discusses the impact of commercialism on parenting and teaching and ways that parents and teachers can respond.

Young Children's Developmental Vulnerabilities

Children are vulnerable to the techniques used by marketers to sell them products because of how they think. They generally focus on the dramatic and concrete aspects of how things look and have a hard time looking beneath the surface at motivations,

intentions, and abstract ideas. Their thinking is more like a slide than a movie—that is, they tend to look at one factor or idea at a time, not multiple factors and the relationships between them. This makes it difficult for them to understand the logic underlying specific situations; for instance, distinguishing a program from an advertisement or the cause and effect within an ad.

Because of how they think, when young children see advertising or product-based media, they focus on the most salient, concrete aspects of what they see and do not put the information they see about the product into a meaningful context. This means that they have a hard time distinguishing between programs and commercials. If a product is different in one dramatic way from something they already have, they think it will be exciting and often want it. In addition, they have trouble understanding the intention that underlies commercials, that is, to sell them something.

There are very clear connections between the characteristics of young children's thinking and the strategies used by marketers. For instance, because young children cannot think about what lies underneath the surface, such as intentions for behavior, they are unlikely to realize that the children in an ad for a toy appear to be happy and having fun because they are actors being paid to look that way. Thus, the children watching it think the toy will make them happy too, so they want to buy it. When the product does not bring happiness or perform as the ad seems to promise, children can be left feeling disappointed, without the logical causal thinking ability needed to fully understand why. Thus, they learn little from the experience about consuming and instead quickly look at the next ad to figure out what to ask for next, even if it is different in only one way from what they had before.

Impacts Seen on Children, Parents, and Teachers

Commercialism is seen as a factor contributing to many of the development, learning, behavior, and health problems today's young children face. Commercialism geared toward children also can have an impact on parents and teachers.

Play

Some research has shown changes in how children play as a result of the increase in toys that are linked to the media. These media-linked toys, which are huge moneymakers for the media and toy industries, teach children that when they play, they should use these highly structured toys to *imitate* the characters and try to replicate what they see on screens, not create their own unique, imaginative play. In the case of TMNTs, this means having the toy characters fight with each other, and little else. When children are merely imitating what they have seen on screens, with toys that keep them focused on that imitation, they are more likely to develop short attention spans, flit from thing to thing, and be at loose ends when they have free time or during “free play.”

The onslaught of marketing can also tell young children that they *need* to use the media-linked toys to *know how to play*, rather than use their own creativity and imagination to develop their own characters and scripts, problems and solutions, from their own direct experience. Jean Piaget’s work on children’s play taught us that following someone else’s script is imitation, *not* play. When children become dependent on toys such as those from the TMNT movie, they often have a hard time coming up with their own interesting and meaningful problems to work on and solve in their own unique ways, which is an essential contribution of play in helping to lay the foundation for learning, development, and well-being. Diane Levin and Nancy Carlsson-Paige first documented this phenomenon in their survey of several hundred teachers for their book, *The War Play Dilemma*. The book reported teachers’ concerns over young children’s endless running around, imitating the Ninja Turtles karate chops and hurting each other but rarely developing it further into meaningful play. It can seem as if much of today’s play is becoming remote-controlled by the media and marketing forces rather than children coming up with their own interesting problems to work on in their play and being resourceful and meaningfully engaged players in their own right. Levin discusses this issue in depth in *Beyond Remote-Controlled Childhood*,

based on years of working with teachers and parents to promote play, and refers to it as *problem-solving deficit disorder* (PSDD).

Gender Roles

Extremely wide gender divisions characterize marketing to children. Marketers exploit the fact that children are working to define their gender as girls or boys from a young age and that, because of how they think, they use concrete differences they can see between girls and boys to do so. Violence in media, toys, and advertising is used to market to boys; that is, boys have to be tough, strong, and ready to fight. The original model used for marketing whole lines of products to children linked to violent media was the 1977 *Star Wars* movie, which predates deregulation of television by a few years. It was the first movie to have toys that were highly realistic replicas of almost everything children saw on the screen. Marketing products to children through films was not regulated the way television marketing was at the time.

After *Star Wars* and the deregulation of television in the early 1980s, using violent themes in movies and television programs became a common practice for marketing products to boys through violence. *Teenage Mutant Ninja Turtles* and then *Mighty Morphin Power Rangers* followed, each next success having more violence and more products. At the same time, many teachers voiced concerns about the increased levels of violent play they saw in their classrooms as boys imitated the characters they saw on screens, which Levin and Carlsson-Paige discuss in their book about war play. Popular new versions of these successful movies and product lines continue to resurface today, with huge success. For instance, on August 31, 2014, after the release of the most recent *Star Wars* movie, Walmart had 1,675 *Star Wars* products on its website. This is happening despite the fact that already in 2000, the American Academy of Pediatrics had concluded that media violence can have harmful effects on children’s attitudes and behavior.

Appearance, sexiness, and the color pink are used in media to market to girls, so that they will look appealing to boys and try to be prettier than

other girls, wanting to buy products to make them look pretty. Although there have been sexualized female characters in many of the popular violent media packages, the most successful sexualized themes have been aimed directly at girls. And probably no line of products has been more successful at this kind of marketing to young girls—being pretty and sexy in order to capture your prince—than the Disney Princess line. On August 31, 2014, Walmart had 1,223 Disney Princess products on its website. Peggy Orenstein discusses her struggles to deal with this issue with her own daughter in *Cinderella Ate My Daughter*. Levin and Jean Kilbourne discuss in *So Sexy So Soon* how detrimental the marketing of sexualized behavior and appearance can be on girls, including in their relationships with boys, from the early years through adolescence. In 2007, the American Psychological Association voiced concern about the impact of early sexualization on mental health and healthy sexual development.

There are always new products on the market that are a little different than what came before; this is enough for young children, because of how they think, to decide they need to have those products to be successful girls or boys. There is very little overlap between what is marketed to girls and boys—few activities or products they can share—so that even their bicycles need to be blue or pink.

Relationships

One of the tasks of childhood is learning how to have caring connected relationships, at least in part through having give-and-take interactions with others. Because how one looks (for girls), how tough one is (for boys), and the objects one owns have become more and more important, children have begun to treat themselves and others more and more like *objects*. They learn to judge themselves and others by how they meet the tough guy and sexy girl stereotypes—looking right, acting right, and having the right objects. Levin has referred to the behavior resulting from this objectification of self and others as *compassion deficit disorder* (CDD)—that is, children not developing

the caring, connected, give-and-take relationships at the rate that they should, and being more likely to bully and tease each other than in the past. For instance, reports of rising levels of bullying and teasing in schools at younger ages, in the years since the escalation of media and media marketing to children, have led to a growing number of books and resources on bullying for children, parents, and teachers, including items on the websites of the U.S. Department of Education and the American Academy of Pediatrics.

Obesity

According to the Centers for Disease Control and Prevention, levels of childhood obesity in the United States have more than doubled since 1980. This time span coincides almost exactly with the number of years since deregulation, when marketing fast food to children began to rapidly increase and continues to do so today. In fact, by 2012, the fast food industry spent \$4.6 billion to advertise mostly unhealthy products, and children and teens were the key audiences for that advertising (Harris et al., 2013).

Parenting

Commercialism geared toward children often targets or influences their parents. In her book *Consuming Kids*, Susan Linn discusses what she calls “the nag factor,” marketing strategies that are designed to get children to ask parents over and over for certain products. Defenders of the marketing industry say that parents could say “no” and not buy what they do not think is appropriate for their children. But, there are many reasons why this cannot solve the problem, including that there are too many things for parents to say “no” to, children can still be exposed elsewhere, and, when parents will not buy something, children learn to ask grandparents or friends to buy them as birthday presents.

Finally, there are marketing strategies that manipulate parents into thinking they are disadvantaging their child if they do not buy a toy that promises to teach some “important” basic skill,

even if there is no research to support the claim. For more than 15 years, the advocacy organization Campaign for a Commercial-Free Childhood has worked to expose the novel and potentially harmful approaches the marketing industry continues to develop to sell products to children and has even successfully filed complaints with the FTC, for instance, against false advertising claims about the educational benefits to children of Baby Einstein products.

Teaching

Children learn best when they are interested in what is being taught. Today, there is often a chasm between what teachers are trying to teach and what children are interested in learning. Children's deep interests are increasingly connected to the values and messages of commercial culture with its heavy emphasis on consumption, appearance, violence, sexuality, and celebrity. PSDD can make teaching harder by reducing children's interest in finding and solving problems in their own unique ways, which is essential for meaningful engagement in the learning process. PSDD can also threaten children's belief in their own ability to master the skills and concepts schools teach.

Responses to Commercialism

More research is needed to determine the precise impacts of commercialism on young children, and many organizations have called for increased restrictions on marketing directed toward children. But in the absence of stricter regulation, those who work with parents can help them create rules and routines about media use and setting their own limits on what is purchased, when, and how.

Parents and those who work with children can help children find interesting problems to work on in their play, develop problem-solving skills, and make sure they have long periods of uninterrupted time for play at home and school. They can help them find meaningful content to bring to their play and interesting problems to work on solving in their play, as well as learn to use open-ended

materials such as Play-Doh and blocks. They can counteract the gender stereotypes presented in commercial culture by helping children expand their concepts of what they can do as boys and girls and develop a broad range of interests, skills, and behaviors. Finally, they can help children develop empathy and caring relationships by establishing safe channels of communication for children to talk to them without fear of being embarrassed, ridiculed, or punished and by helping them learn positive ways to solve problems and conflicts.

COMMON CORE STATE STANDARDS

The Common Core State Standards (CCSS) are educational goals for Grades K–12 in the English language arts (ELA) and mathematics. The standards are a result of a collaboration of several U.S. states. They were written under the auspices of the National Governors Association and the Council of Chief State School Officers with the financial support of the Bill and Melinda Gates Foundation. More than 40 states have adopted CCSS as their educational standards.

The ELA standards address reading, including foundational skills (e.g., phonological awareness, phonics, fluency); writing, speaking, and listening; and language (e.g., grammar, usage). The math standards include counting and cardinality, algebraic thinking, numbers and operations (e.g., base ten, fractions), measurement and data, and geometry.

Rationale for the Standards

Since 1991, U.S. states have been required by federal law to establish educational standards for elementary and secondary schools and to evaluate student progress toward those standards. However, as the federal government began holding schools accountable for reaching their standards, many states lowered standards to ensure success.

The CCSS were written to guide states to higher outcomes. Proponents noted the relative educational success of other nations on international tests of student performance and that many U.S. students were not prepared for college and careers. Analyses show that the CCSS are more rigorous than past state standards.

In response to those concerns, 48 states participated in writing the CCSS (all but Alaska and

Texas). In 2010 and 2011, states adopted the standards through their usual approval processes. In all, 46 states adopted the standards (including Minnesota, which adopted the ELA, but not the math standards), but by 2014, Oklahoma, Indiana, and South Carolina subsequently dropped CCSS, and other states were considering similar action.

Controversies Over the Standards

Political opposition to the standards began to emerge in 2013. This led some states to reverse their adoptions, but dropping CCSS proved easier than replacing them. Indiana, for example, replaced CCSS with a nearly identical set of standards, and some other states have done no more than rename the standards.

Controversies have focused on several issues. Opponents claim that the standards represent a federal takeover of schools, despite the lack of federal involvement or financial support in the writing or adoption process. However, the federal government encouraged states to adopt CCSS through its \$4.4 billion Race to the Top grant competition, which called for states to submit reform plans that included improved standards and assessments. Critics have also blamed CCSS for unpopular testing policies, concerns stoked in part by the federally supported creation of new tests aligned to the CCSS. However, non-CCSS states also are required by federal law to test student performance.

What Makes CCSS Different

The CCSS differ from what they replaced both in how they were developed and with regard to the specific ELA and math skills being promoted. CCSS began with the development of college- and career-readiness standards for 12th graders; then standards for the earlier grades were extrapolated based on these final outcomes. Previous standards were usually written from kindergarten up without a consideration of the ultimate end points.

Also, these standards were written according to the “fewer, bigger, better” philosophy. That means they emphasize a greater focus on fewer topics. The CCSS do not provide a detailed list of

all possible skills and knowledge students might need to achieve the outcomes. Unlike past state standards, the CCSS are less a curriculum than a set of learning goals.

The math standards represent some important shifts from past practices. Not only do they encourage the teaching of fewer mathematical topics with a greater emphasis on the topics that are included, but these standards are more coherent within and across grade levels. Studies show that American math curricula are less coherent than those of countries with high performance on international math tests and that the CCSS standards are more coherent. The math standards aim to develop a deeper conceptual understanding of mathematical processes while maintaining an emphasis on fluent calculations.

The ELA standards also include many new features. Instead of emphasizing reading skills alone, they require that students be taught to read texts of particular levels of difficulty at each grade in Grades 2 through 12. CCSS place a greater emphasis on informational text, as opposed to literary texts; students are to spend equal amounts of time reading such texts. The standards focus on argument in reading, writing, and oral language. Argument requires a careful use of evidence and a consideration of counterarguments and alternative explanations. Students are also expected to spend more time writing about text, analyzing and synthesizing information, and on the use of digital resources in their reading, writing, and research.

As of 2015, some states were considering whether to continue using the CCSS. In addition, several states decided not to use the tests developed by the Partnership for Assessment of Readiness for College and Careers (PARCC) and Smarter Balanced Assessment Consortium, and these tests were undergoing revision as well. In spring 2015, students in 11 states and the District of Columbia took PARCC exams, while 18 states participated in the Smarter Balanced test.

COMMUNICATION DISABILITIES

Communication disabilities refer to a number of disorders that affect the processes of hearing, language, and/or speech production. Young children who experience communication disabilities may demonstrate a range of difficulties that impact their everyday functioning and participation in the classroom. This entry provides information about the various types of communication disabilities, their possible causes, and related disorders. It then describes a case example to explain the implications of communication disabilities for early learning and give examples of best practices for early intervention and the classroom.

Types and Causes of Communication Disabilities

Communication disabilities can be categorized into three broad types: speech, language, and hearing, all of which can be further subcategorized. This section explains each of these categories.

Speech Disabilities

Speech disorders are those that affect the articulation of speech sounds, fluency, or vocal quality.

Young children who experience these kinds of communication disabilities often have difficulty expressing themselves effectively and efficiently. Unintelligible speech can lead to barriers between communication partners including parents, peers, and teachers that may have adverse effects on a child's academic and social-emotional development. The following disorders, with variations in severity, fall under the broad category of speech disorders.

Speech Sound Disorders

The term *speech sound disorders* can be used to describe a wide array of different articulation (form of speech sounds) and phonological disorders (function of speech sounds). The term *articulation disorder* is typically used to describe difficulties producing speech sounds as a result of a structural malformation (e.g., cleft palate) or motoric impairment (e.g., dysarthria). A child with an articulation disorder may substitute, add, or change sounds resulting in unintelligible speech. Many young children make sound substitutions, particularly for challenging sounds, such as an “r” sound. In this instance, a child may substitute a “w” sound for the “r” sound (e.g., “wing” for “ring”). Speech errors are part of typical development; however, if errors persist beyond the expected age, the child may have an articulation error.

Specific disorders that are included under the umbrella term of articulation disorders include the following:

Childhood apraxia of speech: a motor speech disorder that impacts the planning and coordination of muscle movement needed for speech production and may be caused by circumstances such as muscle weakness or paralysis

Dysarthria: a motor speech disorder resulting from weak, paralyzed, or poorly controlled muscles caused by damage to the brain, damage to the nerves, or neuromuscular disease

Orofacial myofunctional disorder: a speech sound disorder resulting from an exaggerated protrusion of the tongue between the upper and lower teeth during speech and swallowing

A phonological disorder is typically used to describe erroneous sound patterns that suggest a weakness in the child's underlying phonological system, which is comprised of the sound inventory and rules for a particular language. A child with a phonological disorder may consistently produce an entire class of sounds incorrectly. For instance, sounds produced in the back of the mouth (e.g., "k" and "g") may instead be produced in the front of the mouth (e.g., "t" and "d"). This is known as a phonological process and is common in typical speech development but is of concern if it persists past a certain age.

Many speech sound disorders occur from unknown causes that affect a child's learning of the correct production of sounds or phonological rules. In other cases, the cause is known, such as when a child may have a structural malformation or a sensory-based condition, such as hearing loss. Speech sound disorders may also be secondary to other disabilities such as a genetic syndrome (e.g., Down syndrome), neurodevelopmental disorders (e.g., autism), or neurological disorders (e.g., cerebral palsy).

Fluency

Fluency refers to the rate, smoothness, flow, and effort of speech. Disfluent speech, such as pauses, word interjections, and whole-word and phrase repetitions are typical of all speakers, including young children. Disfluent speech becomes a concern when it is persistent and characterized by stutter-like disfluencies, including part-word or sound/syllable repetitions. These disfluencies may be paired with visible tension of the speech musculature and neck, avoidance behaviors, and anxiety. Childhood fluency disorders can appear in children as early as 2½ years of age, and the majority of children who stutter show symptoms before the age of 5. The causes of fluency disorders are not well known, but research has shown that factors may include genetics and coexisting motor speech disorders.

Voice

Voice refers to the sound produced by the larynx and involves pitch, loudness, and quality. A

voice disorder, also known as dysphonia, can significantly interfere with a child's communicative abilities. Childhood dysphonia is typically categorized as infectious, congenital, neoplastic, neurologic, inflammatory, and iatrogenic. Vocal nodules are one of most prevalent vocal pathologies among young children largely due to behaviors such as shouting, crying, and excessive volume. This inflammatory condition is defined as the swelling of the mid-membranous portions of the vocal folds, which disrupts the vibration of the vocal folds, resulting in hoarseness.

Language Disorders

Language disorders can be categorized into three types: receptive, expressive, or mixed. Each of these types of disorders can impact one or more of the following domains of language:

Phonology: the sound system of a language and the rules regarding the use of phonemes (i.e., speech sounds)

Morphology: the system that governs how morphemes (i.e., the smallest unit of meaning) are used in language to form words

Syntax: the system of rules for governing how words are combined to make sentences

Semantics: the system that governs the meaning of words in a language

Pragmatics: the system associated with the functional and social use of language

Receptive Language Disorder

A receptive language disorder impacts the way in which a child understands language. They may have difficulty following directions, identifying pictures or objects, answering questions, or following social cues during play or in the classroom.

Expressive Language Disorder

Children with an expressive language disorder may have trouble using gestures, putting words together, using pronouns, using correct verb tense, or

making requests or expressing their feelings. They may use shorter or less complex sentences than their peers and may use a limited vocabulary. In some cases, children with an expressive language disorder may depend on a specific set of phrases to communicate. When asked to retell a story or an event, they may have difficulty organizing the information or recalling words. In the classroom, they may have challenges initiating or formulating language efficiently to participate in conversations with peers. As young children develop, these impairments can have an impact on their written language abilities.

The cause of language disorders is often unknown; however, some language disorders are caused by premature birth, low birth weight, hearing loss, poor nutrition, or failure to thrive. Language disorders may also be secondary to other identified disorders, including autism, Down syndrome, fragile X syndrome, fetal alcohol spectrum disorder, and cerebral palsy.

Social Communication Disorders

Social communication refers to the behaviors associated with social interaction, social cognition, pragmatics (both verbal and nonverbal communication), and language processing. Social behaviors range in acceptance depending on sociocultural differences and individual variability, and rules governing interaction are dependent on both the context and communication partners. A social communication disorder may be present if a child is having persistent difficulty with effective communication, relationships, or academic success. A young child with a social communication disorder may also demonstrate issues with language acquisition and, later, written language development.

Hearing Disorders

Hearing disorders can be categorized into three categories: conductive hearing loss, sensorineural hearing loss, and mixed.

Conductive Hearing Impairment

A conductive hearing loss occurs when sound is not effectively conducted through the outer ear to

the middle ear, resulting in reduced sound level. Possible causes for a conductive hearing loss include ear infections (otitis media), fluid in the middle ear, allergies, impacted earwax, or a perforated eardrum. Typically, medical or surgical procedures can resolve a conductive hearing loss. Young children who experience a conductive hearing impairment are usually at risk of developing a communication disability if the duration of the hearing loss is extensive. For instance, prolonged, reoccurring ear infections may impact the development of a child's speech and language skills.

Sensorineural Hearing Loss

The most common kind of hearing loss is sensorineural, which occurs as a result of damage to the inner ear (cochlea) or cochlear nerve. Depending on the severity, the onset of the hearing loss, and intervention provided, young children may experience a range of speech and language impairments.

Children who experience hearing loss earlier in life will experience more serious effects in terms of speech and language development. These effects typically impact the development of vocabulary, sentence comprehension, and speech sound production. Thus, academic achievement and social-emotional development are often affected as a result. Typically, an interdisciplinary team of professionals develops an intervention program to address possible communication barriers.

Implications for Early Learning: A Case Example

The following case example is a composite of actual cases of children with communication disabilities. Molly is a spirited, inquisitive 4-year-old girl who enjoys playing with her older siblings and parents. At 2 years of age, Molly's parents noticed that she was still using gestures and single-word utterances to communicate her needs. She was highly frustrated and would tantrum quickly when others could not understand her requests. Although she understood many two-step directions, her expressive vocabulary was limited to 15 words, including "mama," "dada," and "baba" for

baby. As she approached 3 years of age, her parents were concerned that her vocabulary was still very limited. Additionally, Molly's articulation was still immature in form, as words such as "baba" were not evolving to more adult-like forms (e.g., "baby"). Molly received early intervention services that focused on her communication skills, and a great deal of progress was made in terms of Molly's expressive vocabulary and mean length of utterance.

As Molly progressed to preschool, she transitioned to an individualized education program (IEP), as she continued to qualify for speech and language services. Most notably, Molly's vocabulary was still underdeveloped and she had difficulty learning the correct verb tense. She would frequently have trouble with word retrieval, which led her to use generic terms such as "that thing" when describing an event. Although her intelligibility was improving, Molly continued to demonstrate speech sound errors that are typically resolved by preschool age, making it hard for her peers to understand her at times.

Through the IEP, Molly receives one-on-one services with a speech-language pathologist (SLP) to target her expressive language and speech sound production. The SLP also works with Molly's teacher to find ways to scaffold, or provide continuing guidance for, certain tasks in the classroom that are verbally demanding, such as story retelling or show and tell. Because many young children with a history of speech and language disorders are at risk of developing reading disorders, Molly's teacher and SLP work together to give Molly intensive instruction of phonological awareness, including letter names, letter-sound correspondence, and syllable segmentation and blending.

Interventions and Best Practices

Early Intervention

For Molly, early intervention was a critical piece to her progression. Early intervention has been shown to be an effective service for children from birth to 3 years of age. Some of the most effective

strategies of early intervention involve parental training and direct involvement. Early interventions may focus on the increase of language development, improvement of speech sound production, or social communication skills. Some children may be taught to use some sign language to bolster their language development. Children who present with more severe speech or language problems may be recommended for augmentative and alternative communication, such as picture communication boards or electronic devices.

Preschool and Beyond

Like most children with communication impairments, Molly's difficulties manifested differently over time as she matured and experienced new contexts. Although Molly has shown progress in her expressive language skills, it is likely that she will encounter new challenges, particularly in the classroom, as the curriculum becomes more demanding. Molly may face persistent struggles when writing becomes an academic focus, resulting in frustration related to sentence construction, grammar, and organization.

For children like Molly, the classroom can be a place where demands related to writing, reading, and oral communication can present barriers to learning and demonstrating knowledge. It is often the case that children with communication disabilities need both one-on-one services—to learn strategies to manage difficulties and practice skills intensively outside of the classroom—as well as well-designed classroom environments that minimize barriers. In some cases, the requirements of the classroom are fixed (e.g., standardized testing), but in many cases, there is great opportunity for flexibility. Take the case of Molly in the preschool classroom. If the goal of the lesson is to retell a story so that students learn story grammar (e.g., characters, sequence, resolution), then it is possible that students could show their retelling skills through other means beyond oral communication. Molly might draw pictures or choose images to create scenes that demonstrate her knowledge of the events. If in fact the goal is to retell a story *orally*, then Molly might first practice drawing or

using pictures before she attempts to retell the story orally so that she may first practice with the right support. The practice of designing appropriate options for classroom experiences is referred to as universal design for learning and serves as a framework for inclusive education.

COMMUNITY PARTNERSHIPS

There has been growing recognition of the importance of community partnerships, which are the planful joining together of various community, county, state, and federal groups and programs to best meet the needs of young children and their families. The return on financial investment in quality early care and education, according to well-known longitudinal research such as the famous HighScope studies, is high, with more than a dollar return on an early childhood investment of one dollar (Kirp, 2007). Sociologists have lamented the fact that social networks and connections in communities have dissipated in recent years, with young people of all ages receiving less investment and attention from adults. Efforts to build communities that can support children and families are “money in the bank,” building the social capital that makes a strong and productive society.

This entry discusses theories that relate to community partnerships, strategies for community partnerships, and types of entities that often participate in partnerships. It then describes some well-known examples of community partnerships.

Helpful Concepts

Community partnerships are most likely to make a wide-reaching and sustained impact when they are theory-driven; that is, they are derived from current concepts that are based on empirical research and other knowledge sources.

Ecological Systems

Perhaps the most important concept for designing community partnerships is Urie Bronfenbrenner’s famous and still highly relevant ecology of childhood, described in his 1977 article “Toward an Experimental Ecology of Human Ecology,” consisting of multiple levels of systems that all interact to affect and shape the lives of children and families. The *mesosystem* includes the interrelationships among the settings “containing” children (e.g., families, peers, school, church). The *exosystem* includes

the institutions of society, such as employment, mass media, government, transportation, housing, health, and the like.

The adequate presence of these infrastructures in the lives of families and children enables a “family to function as a child rearing system” (Bronfenbrenner, 1974, p. 55). It is the settings and institutions of the mesosystem and exosystem that show how crucial community partnerships are that not only work to ensure that these fundamental elements are present in the lives of young children but also provide focus and definition for community partnership building efforts. The partnerships work to ensure that these components are provided and that relationships among those providing them are harmonious.

To develop successful partnerships means building a coherent system for organizing, administering, and evaluating service at the multiple ecological levels that addresses the interactions among these levels. This perhaps is the greatest challenge to communities. Karen Ponder suggests that a centralized system at the state level is an optimal way of providing unified, goal-oriented, smoothly functioning partnerships.

Early Intervention

In general the term *early intervention* is associated with the practice of securing services for very young children with developmental delays or who are otherwise considered to be “at risk.” On the assumption that an intervention is a group of planned actions intended to alter the course of development in a positive way, it is put forth here as an important concept in community partnership building. Early intervention approaches are applicable not only to infants and toddlers but also to preschool children who are at risk because of poverty or some other deleterious condition or situation or who are essentially normal but for whom community resources can serve as a positive developmental influence over time.

Since the inception of early intervention programs in the 1960s, it has been found that those that were “comprehensive,” that is, that were broadly based and involved families, were linked

to successful outcomes such as greater school readiness. The contemporary notion of community partnerships that plan, assemble, coordinate, and deliver multiple services to young children and their families is a means of providing comprehensive services. In this way, community partnerships provide early intervention.

An important aspect of community partnerships is to be concerned with longitudinal connections so that children experiencing the benefits of an early childhood intervention can have them sustained by appropriate activities as they grow older, in line with the notion that as long as quality intervention continues in some form, early outcomes are more likely to be sustained (Bronfenbrenner, 1974).

Developmental Assets

The Developmental Assets approach is based on a large and continuing body of research by the Search Institute, a nonprofit research and training group focused on youth development. These strength-based assets name specific resources (external assets) that are provided by others (family, community, government) that enable young people to thrive, and positive developmental outcomes are expected as a result of the provision of these experiences. Used worldwide, this framework has been adopted by many communities to help guide child, youth, and family supports and services. Eight communities have been studied extensively to identify how communities choose to adopt the Developmental Assets and coalesce to design and implement the means to help the community’s children and youth attain the assets. The assets are comprehensive, easy to understand, and research-based and can serve an important function in providing a clear goal for community-building efforts that then become what Richard M. Lerner and Peter Benson call “asset-building communities.”

Strategies for Community Partnership Building

Any effort to design and deliver services is empowered if known strategies are employed for design,

implementation, and evaluation. Where community building is planful, it is more likely to be successful. Researchers have described several strategies to build effective community partnerships:

Sense Opportunities. Leaders and others need to be intentionally aware of opportunities and needs that can be met through community partnership building. Knowing trends in development and services, being aware of current and emergent social problems, checking out funding programs, and developing and maintaining communication networks all contribute to the impetus to form a community partnership.

Know the Territory. A crucial preliminary step of studying the community needs to take place. It is important to know the dynamics, socioeconomic situation, and the demographics of the area in which partnerships may be created and conducted. However, research on community development is not as extensive as that on the developmental psychology of the individual. One pioneering study of communities is the Project on Human Development in Chicago Neighborhoods (Earls & Buka, 2000). This study has identified ways of understanding the organization of communities and ways of measuring various community characteristics.

The point is made that community factors may play a stronger role than is usually thought. For older youth, but with relevant application for pre-schoolers, the Search Institute has studied strategies for community building extensively and emphasizes that understanding a community's social norms, relational patterns, and informal networks is essential for effective community building (Nakkula, Foster, Mannes, & Bolstrom, 2012).

Be Aware of Cultural Factors. A partnership effort can sink or swim depending on participants' sensitivity to cultural factors in both communities themselves and in the organizations planning to join together. Activities need to be conducted to identify both differences and commonalities in values. Commonalities can be used as entry points to building mutual understandings about differences and ways of addressing them. Transparency, open

communication, and mechanisms for seeking input from all constituencies are needed. The people who live in the community and will be served by the partnership must be involved and give input from the beginning.

Be Planful. Being planful means coming together and in general applying a planning or strategic planning model to the task of establishing a purpose or mission, goals, and objectives (specific outcomes), a rationale, target audience, activities, and initiatives designed to attain the goals. However, it is important to consider the time range of the plan and have the ability to adjust long-term strategic plans, because so much is unpredictable.

Get Started. "The best is the enemy of the good," a saying usually attributed to the French writer Voltaire, contains wisdom for those developing community partnerships. Although community partnership builders ideally have a vision and a plan, it is best to get started before the plan is perfect. There is a rationale for this based on dynamical systems theory, which says that once an action is taken, effects or reverberations are felt in the wider system of which it is a part. Feedback enables more informed guidance to be applied as the project moves along.

Decide on the Nature of the Partnership. There are different forms and structures for community partnerships. A coalition is akin to the concept of a community partnership; in essence it is an agreement among a group with a common interest or concern to join together. An initiative may focus more on addressing the needs of a heretofore unexamined area (i.e., taking action or showing initiative). A collaboration is a joining together to share the work on a project of mutual interest.

Identify and Agree on Desired Outcomes. The effort of forming community partnerships is relatively useless if there are not identifiable and positive outcomes for children. These outcomes should be based on respected theoretical and empirical knowledge of child development. Possible outcomes of partnerships might include, as suggested

by Ponder, more recognition by the public of the importance of young children as a resource, school readiness, higher levels and effective use of funding, and high-quality programs with a well-prepared professional workforce. The clear statement of the knowledge base of the outcomes also facilitates the design of effective evaluation strategies.

Build in an Evaluative Component. Proposals for programs and interventions often do not include a strong evaluation component, which can result in the failure to receive funding. It is important to provide a well-designed evaluation plan. Having carefully defined the desired outcomes and activities to attain them at the initiation of a partnership sets the course for an evaluative component that enables periodic assessment of the partnership and, at given time points, of progress toward attaining outcomes and what actions contributed to them. Such periodic examination can enable approaches to be altered if they are identified as not being effective. Confirmatory program evaluation (Reynolds, 2005) is a sophisticated method in which the explicit theory of the program stated prior to its implementation is examined to provide greater evidence of what specific interventions in a program account for attaining the outcomes.

Common Areas for Partnership Development

Given that the combinatory potentials for partnerships are almost infinite, it is helpful to know some of the areas in which partnerships have already been forged. A community partnership can be between only two entities, for example, a preschool and museum, or it can embrace programs and agencies that address multiple levels of needs. Entities that can be involved in these partnerships include

- educational institutions (e.g., schools, care centers);
- religious institutions (e.g., churches, synagogues, mosques);
- recreational facilities (e.g., parks, playgrounds, YMCAs and YWCAs);
- neighborhood organizations (e.g., community and neighborhood centers);
- cultural organizations (e.g., museums and organizations focusing on art, music, and drama);
- health organizations (e.g., hospitals, clinics);
- law enforcement (e.g., police, legal organizations);
- housing groups (e.g., public housing projects, apartment complexes);
- mental health organizations (e.g., treatment centers, special needs programs);
- child welfare organizations (e.g., social service agencies);
- funders (e.g., foundations, financial institutions, governmental grant programs [several community organizations may collaborate in applying for funding]);
- programs serving different age or category groups (e.g., a senior center for intergenerational activities, a camp for special needs children); and
- advocacy groups (e.g., organizations that advocate for improvements in public safety or activities for children).

Some Exemplary Partnerships

Some community partnerships have become widely known and publicized for such characteristics as the scope and comprehensiveness of their design and the attainment of demonstrated positive outcomes. These include the following:

North Carolina's Plan for a Comprehensive Early Childhood System. Numerous agencies collaborated at the state level to generate this plan for an integrated, comprehensive early childhood system.

Early Head Start–Child Care Partnerships. This federal grant program was created in 2014 as part of President Obama's Early Learning Initiative to support local child care and family child care programs serving infants and toddlers of low-income families. The intent is to provide a full-day and year-round program that avoids the fragmentation that too often characterizes the out-of-home care experience of young children.

Chicago Preschoolers Ready to Learn! Initiative. This program of the Chicago Public Schools is designed to provide quality early childhood education. Funding is provided to early childhood programs by the public schools.

Promise Neighborhoods. This U.S. Department of Education program provides funding for nonprofit organizations to specifically focus on community building in low-income neighborhoods.

COMMUNITY SCHOOLS

A community school—sometimes referred to as a full-service school—is a school that strives to address the needs of the “whole child” (e.g., intellectual, psychological, physical, and emotional development) by situating itself within a network of partnerships to offer a complete range of wrap-around support services. The Coalition for Community Schools, a national alliance of organizations and schools engaging in this work, defines a community school as “both a place and a set of partnerships between the school and other community resources.” Each community school partnership is a network of school faculty and staff,

parents, and organizations within the community, working together to assess and respond to the various needs of the school's students through social services, physical and mental health services, extended-day educational services, and adult education programs.

Historically, the notion that schools should be able to respond to a broad range of student needs has existed for over a century with its early roots tied to the reforms championed by Jane Addams and John Dewey. However, the strategic approach most often understood today is the community school approach begun in the early 1990s with several initiatives across the United States to develop community schools within high-poverty neighborhoods. The impetus behind this more recent resurgence is an attempt to ameliorate the effects of poverty through a wide range of support services going well beyond the classroom. The rationale of this approach is that the social problems generally associated with poverty (e.g., poor health, unstable housing, and inadequate preparation for school) stand as a barrier to students' academic success and limit the ability of schools to play a role in breaking the cycle of poverty.

Current theories of community schools posit that schools and their community partners can mitigate the relationship between poverty and student achievement indirectly by addressing the deleterious effects of poverty in those students' lives. Community schools aim to achieve these goals by building mutually beneficial and supportive relationships across schools, community organizations, and families to bring together community partners that can provide access to needed supports.

The Community School Approach

There is not just one model for what could be described as a community school. This diversity is intentional and can be attributed to the needs of the community that each school serves and the nature of the founding partnership that supports the school. Although there are many different approaches to the formation of community schools, all strive to place the school and its students at the center of a network of support. Some community

schools are born out of school or local community initiatives to improve the school(s). Others are created when a community-based organization decides to marry its services with a school to offer a variety of on-site support services. Other community schools are developed through university–community partnership networks in which a large established university takes on the responsibility of improving schooling and community. A community school can be created as a new school but is more often created from a preexisting traditional school (occasionally as part of a turnaround strategy) in an effort to address unmet student needs and improve academic outcomes.

Regardless of their structure, community schools tend to share three aims: (1) to provide rigorous, quality instruction; (2) to offer a comprehensive array of supportive services to children and their families; and (3) to build lasting relationships across schools, families, and communities. Most community schools also have a dedicated staff member in place to oversee the day-to-day operations of the school. Usually this person is a licensed social worker who works very closely with the school's principal to ensure that the social services, physical and mental health services, and extended learning activities are well integrated into the school's core instructional and administrative structure.

Despite the generally agreed upon need for schools of teacher education to provide formal support for preservice teachers around the social, cultural, and linguistic needs of their students, most schools of education offer inadequate preparation for teachers to understand and respond to the needs of their students from a strengths-based approach. Many community schools offer their staff professional development on how to engage families and communities and draw on their strengths.

In addition to supporting and educating teachers, successful community schools continually work to engage and educate families in the school's day-to-day work and decision-making processes. Parents are invited to visit regularly and, if they have the time, volunteer in schools. The schools also respond to the needs of the parents by offering classes such as adult education for high school

equivalency diplomas, English for speakers of other languages, and financial literacy.

Of course, community school partnerships fall across a broad spectrum of development from loose systems of informal support that aim to encourage improved student learning to highly formalized and codified community schools with a wide range of community supports designed to undergird student learning by providing support to students and their families. An established, well-funded community school might offer all possible supports and services at a high level of fidelity while a school just adopting a community school approach might only be able to offer a few services and have to rely more heavily on volunteers.

How Community Schools Work to Attenuate the Impacts of Poverty

In addition to the financial costs that work against families living in poverty who are striving to support children along their educational path, children from poor families are also disadvantaged by what educational economists term *opportunity costs*. Better educated, wealthier parents are more able to offer their children myriad opportunities to succeed in life than less educated, poor parents. Some of these opportunities are easily monetized, such as access to better health care, a stable housing situation, and educational and extracurricular activities outside of school. Other opportunities are more difficult to value with a dollar amount, including access to more academic language and discourse at home, examples of family members and friends who have achieved high levels of education, and complex social networks that offer expertise in a wide range of fields. Simply because of the life they were born into, poor kids are often less prepared for success in school and their later careers. Research finds that youth from low-income backgrounds suffer these opportunity costs and generally achieve at lower levels than their more advantaged peers.

Community school partnerships aim to reconcile the relationship between socioeconomic status and academic achievement by providing a full complement of supportive services that extend well beyond the regular school day schedule. To

accommodate these services, most community schools are open from early in the morning until late in the evening and on weekends as well.

Research tells us that people from lower income backgrounds are more likely to experience health challenges, including chronic diseases such as diabetes and asthma, poor nutrition, and lack of access to quality health care. To address these difficulties, some schools are able to situate medical and mental health offices within their school buildings. Other community schools build relationships with medical centers and arrange health, dental, and vision screenings at the school for children and their families when possible. Additionally, many community schools offer nutrition classes for parents and children to introduce healthy and affordable meal options that they can prepare at home.

The Importance of Early Intervention

Researchers from disciplines such as developmental psychology, developmental-behavioral pediatric medicine, cognitive neuroscience, neonatology, and public health that carry out research on child brain development point to the importance of supporting children's development from birth, and even prenatally. Poor children are the most likely to miss out on these needed supports. Research tells us that by the time the typical child living in poverty starts school, he or she is already at a disadvantage as compared to his or her more affluent peers. Furthermore, these students are frequently at a high risk of eventually dropping out of school. For these reasons, many community school advocates argue that programs focused on elementary and preschool education can have the greatest interventional effect in helping to bridge the achievement gap and better engage students from low-income communities.

Research on traditional schooling shows that the achievement gap continues to grow after children have entered school. Community schools argue that one major cause of this is chronic absenteeism. Community schools have many procedures in place to improve student attendance. By tracking student attendance regularly and on an individual basis and engaging parents and partners in the solutions,

community school partnerships can be successful in improving and then maintaining regular attendance at school.

Another contributor to the achievement gap that community schools are well positioned to address is summer learning loss. A great deal of research has shown that over their summer vacation, all children lose academic knowledge and the losses are significantly larger for students from poor communities. By embracing models that keep their school open year-round with a host of programs to engage students over the summer, community schools work to ameliorate summer learning loss.

Financing the Community School Approach

Not surprisingly, maintaining a wide host of programs to support a community school can require a substantial monetary investment. Funding to support community schools comes in many forms. Most often community schools are public or charter schools. Because they are aiming to serve students in low-income communities, charging for services is not an option. Fortunately, several federal, state, and local funding streams support community school approaches. Additionally, many private foundations fund community school partnership work. The partnership approach offers a structure that offers stability against fluctuations in funding. More recent years have seen more cities investing in community school models. Any large-scale community school initiative requires a public commitment if it is to remain sustainable. A major goal for all community school partnerships, as their programs grow and mature, is to find sustainable funding approaches.

COMMUNITY–UNIVERSITY PARTNERSHIPS

It is well established that nonacademic barriers to learning, such as emotional issues, behavior challenges, living in poverty, and family problems, can impede a child's ability to be successful in school. Community–university partnerships offer new possibilities for building the capacity of early childhood education to more effectively meet the needs of today's young children by partnering

with faculty and students from across disciplines and capitalizing on the university's goals of civic engagement, interdisciplinary collaboration, applied research, and innovative opportunities for student internships. This entry first discusses what community–university partnerships entail, how these partnerships can address community issues, and the role of collaboration in supporting early childhood professionals and helping families. It then discusses how these partnerships can be developed, implemented, and evaluated, as well as ways they can be strengthened.

Overview

One of the most promising ways that early childhood education can more effectively address the needs of today's young children is to broaden and expand the provision of services using collaborative models. Such collaborative models focus on intraorganizational and interorganizational collaboration and offer an array of possibilities for building the capacity of early childhood education.

Among the array of possibilities collaborative models offer early childhood education is the provision of program-linked services (services provided by university faculty and/or student interns near a program and formally connected with the program), program-based services (services provided by university faculty and/or student interns at a program), or as part of a full-service community agency (integrated services with the agency as a hub). Such community–university partnerships build the capacity of early childhood education by partnering programs with university faculty and student interns from across disciplines (e.g., education, social work, nursing, psychology) to more effectively meet the needs of today's young children.

In part because of its long history of field experience as a central component of professional preparation, early childhood education has been actively involved at the interface of the university and the community for many years. Grounded in education and social principles, these partnerships develop within a civic engagement framework that

calls for the university to engage with issues that the early childhood community names as important and address them collaboratively through service to the community, applied research, and workforce development.

The Emerging Role of Collaborative Teams

Everyone in early childhood education needs the knowledge and skills to work with a range of colleagues through a team approach. Collaboration involves early childhood educators and other professionals sharing information, validating each other's roles, and providing input on which strategies promote positive outcomes for all children. Community–university partnerships can play a critical role in supporting early childhood professionals (e.g., teachers, social workers, nurses, psychologists), in developing the skills to modify and adjust how a team functions as a way to increase efficiency and effectiveness.

Effective collaboration among early childhood professionals is now considered critical for providing services to young children and their families. Although this collaboration may best be presented along a continuum, interdisciplinary collaboration integrates the knowledge and expertise of professionals as a way to reach a common goal through shared decision making and practice. To do so, however, each person must develop the dispositions, knowledge, and skills to collaborate. Yet, early childhood professionals need opportunities to engage in interactive tasks or activities that foster interdisciplinary collaboration. Greater attention is now being given to the potential role that community–university partnerships can play in strengthening this foundation for both preservice student interns and in-service early childhood professionals.

Developing and Implementing Community–University Partnerships

Broadening and expanding the provision of services through community–university partnerships

can take many different forms. However, all participants help develop shared goals and create a protocol to actualize them. For example, an early childhood program has a goal to expand its provision of academic, mental health, and health services. The early childhood program administrator approaches an early childhood faculty member from the local university. The faculty member has a goal to expand the provision of clinically rich, interdisciplinary fieldwork opportunities for early childhood education students. This faculty member then invites social work and nursing colleagues to join the collaborative process. Collectively, they develop a shared goal and a protocol to actualize it as the foundation for the community–university partnership.

A protocol for a referral process can help identify children of concern and obtain permission from families for further evaluation. For example, university student interns from across disciplines might be asked to conduct comprehensive screenings to assess a child's overall health and developmental status. Based on the results of these screenings and in collaboration with program staff, university interns working in interdisciplinary teams and under the supervision of faculty would then determine what, if any, academic, mental health, or health supports or services should be provided.

Depending on the disciplines engaged in a community partnership, university interns from a range of disciplines (e.g., education, social work, nursing, psychology) would begin providing supports and services using a center- and home-based service delivery model. For example, under the supervision of faculty and in collaboration with program staff, university education, social work, and nursing interns might provide a range of supports and services that include individual, small group, or whole group lessons and activities; individual and/or family counseling; and referrals and follow-up regarding issues such as inadequate vision and hearing. The community–university partnership would then hold regular team meetings to ensure a coordinated service delivery. It is also important for everyone involved in the community–university partnership to offer families

meaningful opportunities to become fully engaged in the collaborative process.

Evaluating a Community–University Partnership

In evaluating a community–university partnership, a formative program evaluation design, called *process evaluation*, with the intention of using information gathered to enhance the planning, implementation, and performance of the project can be very helpful. Process evaluations aid in overall improvement by identifying the strengths and weaknesses of a particular program through exploring, through surveys and interviews, the experiences of program administrators and/or staff, university faculty and/or interns, and service recipients.

Even though community–university partnerships can accomplish what may be otherwise impossible in early childhood programs, there can be barriers. These include a range of issues from different disciplinary and professional perspectives or different goals to scheduling concerns. Although one may think of logistical details as minor and ideology as major, research has shown that logistical issues (e.g., difficulties with scheduling, space constraints) must be addressed for community–university partnerships to succeed.

Research also suggests that the organizational culture of an early childhood program can also play a significant role in what supports and services are provided and whether or not the community–university partnership is maximized. Although individuals may enter into the partnership with a collaborative orientation, the experience can become very challenging as a result of confusion around each other's role, frustration with discipline-specific jargon, and differences of opinion in what should constitute a child referral. These challenges can be further exaggerated by what may be perceived as higher status of university faculty and student interns or when organizational structures within the university do not fully support collaboration. Some of the organizational structures within the university that may not fully support collaboration include tenure and promotion

requirements that emphasize sole authorship on publications and full-time equivalent guidelines for faculty teaching loads that create significant barriers to co-teaching.

Next Steps

Community–university partnerships in early childhood education are still in the very early stages of development. Although the information on developing, implementing, and evaluating community–university partnerships in early childhood education is limited, results do point to some interesting points to consider. First, the earlier in the collaborative process that a program and a university can become familiar with each other's roles and expectations, the less likely it is that organizational and communication issues will create barriers to achieving partnership goals. Second, when community–university partnerships are maximized, the links among program quality, staff support, and optimal child outcomes can be strengthened.

Conclusion

In recognition that no one profession can address the academic and nonacademic needs of today's young children, broadening and expanding the provision of services through community–university partnerships is becoming an integral part of early childhood education. Even though community–university partnerships have not yet found their way prominently into the national early childhood agenda, there is every indication that they are on the rise. We can expect to see an increasing number of universities partnering with their early childhood communities as they seek to expand clinically rich, interdisciplinary fieldwork opportunities for student interns, promote university engagement, and assist in addressing community needs.

Developing, implementing, and evaluating community–university partnerships enables early childhood educators to deepen their understandings of the benefits and challenges of addressing the increasingly complex needs of today's young children at

the systems, agency, and stakeholder levels. Community–university partnerships that expand the provision of services in early childhood education also offer new possibilities for supporting optimal outcomes for young children by facilitating efforts to maximize innovative collaborative practices, programs, and policies.

COMPREHENSION

Comprehension is the act of meaning making. Comprehension emerges with other meaning-making abilities, such as the ability for language, writing, and image making. Reading comprehension is the act of meaning making with printed text. Readers comprehend text by constructing a meaning for the text. Reading comprehension—or meaning making—is the goal for reading printed texts.

Learning to comprehend what is read is a developmental process called “emergent comprehension” and can begin as soon as texts are present during a young child’s social interactions. Emergent comprehension is especially important for early childhood education because it describes how children construct meaning with text prior to conventional reading and provides educators and caregivers with a framework for designing developmentally appropriate education. This entry describes the phases of emergent comprehension, origins of the theory of “emergent comprehension,” and children’s unique contributions to emergent

comprehension. The entry also describes how changing texts and digital media are pushing researchers to reframe theories about young children's comprehension as well as controversies about young children's comprehension.

Phases of Emergent Comprehension

Emergent reading comprehension begins via caring, playful interactions between children, their caregivers, and texts. Through these early social interactions, children watch and listen to how others handle and respond to texts. During this early phase, children may not know how to decode text; however, they begin to understand that printed texts mean something to the people around them. Routine interactions with caregivers who share texts with children can support children's comprehension development.

Children listen to stories from storybooks, watch caregivers use texts to get information, view textual messages in their surroundings, and begin to anticipate meanings when they see texts. Eventually, with more interactions with caregivers and texts over time, children learn to seek meaning with (i.e., comprehend) texts.

Research on children's developing understanding of books demonstrates the benefits of routine experiences with books. By about 2 years of age, children can identify what a book is primarily about (i.e., the content of the book) and will sometimes use the book as an object or play prop to represent that content. For example, a book about butterflies might be used as a butterfly during play. By about 3 years of age, children point to (and sometimes call out words for) the images and print within a book. By about 3½ to 4 years of age, children mimic the sounds and cadence of adults' storybook reading and paraphrase the content of the text (sometimes even parroting an adult's reading word-for-word); however, children's words do not necessarily match the printed texts. Notably, these age ranges indicate approximate developmental phases, and age is not as important as the amount of exposure and social interactions children have with texts.

Similar developmental patterns have been shown as children interact with digital texts and media; they become increasingly attuned to and seek out messages and meanings and begin to mimic the ways that others around them read and respond. Phases for emergent comprehension are helpful for conceptualizing long-term patterns that extend from routine interactions as well as changes over time.

Theory Undergirding Emergent Comprehension

Emergent comprehension is based on a heuristic for reading comprehension developed by the RAND Reading Study Group in 2002. This heuristic suggested that meanings are constructed and are unique to each meaning-making transaction. The RAND heuristic demonstrated how meanings are uniquely constructed any time a reader (who has background knowledge, particular abilities, and other unique characteristics) comes to a text (with unique words, particular formats, and genre characteristics) within a reading activity (which sets a unique purpose for the reading). Because there are so many unique contributing factors, comprehension is necessarily a distinctive and individualized construction of meaning.

Likewise, emergent comprehension exists when a child attempts to make meaning with texts, even when those meanings are not conventional or socially acceptable. Researchers Caitlin McMunn Dooley and Mona Matthews revised the RAND heuristic to account for young children's emergent comprehension in 2009. They suggested that children, like more mature readers, construct meanings that are unique to each transaction between the text, the activity, and the child. However, they also suggested that a text is a symbol, and the activity (or purpose) of any reading event is set by way of the child's interaction with someone else. Therefore, the heuristic for "emergent comprehension" involves contributing factors from a child, a symbol, and social interactions.

Children's Unique Contributions to Emergent Comprehension

Children's comprehension is unique to their cognitive, social, and emotional developmental patterns. Children come to texts with child-like concepts about the world around them; thus, young children comprehend text differently from adults. They cannot be taught to comprehend using the same cognitive strategies as adult (or even older child) readers. They do not have similar understandings about the world as older readers. For example, a child may assume a literal meaning to a figurative phrase. Or a child may not yet have the cognitive ability to understand someone else's perspective. Although researchers do not know enough about all of children's cognitive, social, and emotional abilities that contribute to the uniqueness of emergent comprehension, several contributing factors have been noted as especially important: symbolic understandings, narrative understandings, and play.

Symbolic Understandings

Comprehension, or the construction of meaning from print, is a symbolic act. Children's understanding of symbols develops from infancy and continues to develop as they learn to comprehend texts. Print is a symbol system: Letters, words, and texts represent sounds and meanings. However, those constructed meanings will differ from reader to reader. Likewise, text types also carry symbolic meanings. For example, a legal contract has certain formatting, whereas a newspaper looks and feels very different. As children experience "reading"—whether through listening to a caregiver's storybook read-aloud, witnessing adults reading for information, or having any other social experience with text—they construct meanings by considering the text as a symbol.

Children learn to discern one type of text from another by looking at textual elements, formats, and holistic characteristics, often before they are able to decode print. For example, children can tell the difference between an informational book and a storybook before they are able to "read" the

books themselves. In this way, children construct symbolic meanings related to texts and text types.

Children come to symbolic meaning making by following a pattern of moving from indiscriminate meanings to more discriminate meanings with symbols. They may allow for more varied and general meanings for texts, but over time, and with experience with similar text types, they begin to converge on more socially acceptable meanings.

Children also use multiple modalities (e.g., image, gesture, sound, feel) to construct meanings with symbols. They rely on multiple modes for meaning making, and as they develop understandings they dynamically use additional modes to continue the construction of meaning. David Rapp and Paul van den Broek call this "dynamic text comprehension"—the act of a reader to use what is already known about a text to continue to build meaning.

Narrative Understandings

Perhaps because most research to date has been done with storybooks, much has been written about how children's narrative understandings contribute to their comprehension development. However, the mode of narration does not seem to matter; whether in the form of storybook read-alouds or in the form of oral story-telling, children who engage in stories with caregivers perform better on early assessments of comprehension. More important than the mode of the narrative is the process for adult-child interaction during engagements with narratives. Children who are given opportunities to discuss and question stories they hear or watch (via video) or see in storybooks are better at identifying narrative elements such as causality and sequence (e.g., the story's beginning, middle, and end).

Interactive Play

Children will sometimes demonstrate their comprehension of texts by simulating the use of those texts in their play. This is true for digital and paper texts. For instance, children might play with long paper lists as "receipts" when pretending to be at a store. Or they might pretend to read Internet sites

when pretending to choose a movie to go to with a friend. Several studies have shown how children haggle over meanings of texts during playful exchanges. They do not always agree on what texts mean, but they do seem to enjoy simulating meaningful engagements with texts. In this way, children are exploring what textual meanings are possible as well as what meanings are socially acceptable.

Changing Texts

As digital texts become more prevalent, researchers are growing aware of how children's experiences with texts are different now compared to 10 years ago. This is notable because children have not changed, and they do not perceive any change—a world with digital texts is all that they know. However, the research on comprehension needs to continue to evolve as texts evolve.

Some of the affordances of digital texts are particularly significant for comprehension. For example, the capacity for digital texts to engage readers in multiple modes simultaneously is somewhat new (a caveat: Picture books have always provided text and image simultaneously). Given that children use multiple modes to construct meaning, researchers are investigating how much is helpful (or hurtful) to young readers when it comes to constructing digital texts. Another difference that is prevalent in digital texts is the interactivity that is possible—even in the absence of physical presence. Texting, interactive websites, video conferencing, text messaging, and digital stories afford real-time interactivity. Children see adults use these texts. They mimic their use and sometimes may engage in text-based interactions themselves.

Controversies and Disagreements About Emergent Comprehension

There is some controversy over whether children can be considered as “comprehenders.” Until the early 2000s, many early literacy researchers believed that comprehension could ensue only after children mastered decoding. The National Reading Panel published a report in 2000 that suggested that comprehension instruction was especially important to

children in upper elementary grades but did not suggest instruction prior to decoding. Similarly, the National Early Literacy Panel report, published in 2008, reported that little to no research investigated comprehension among young children.

Perhaps the paucity of research on emergent comprehension is due to an overreliance to date on the “simple view of reading,” developed by researchers Phillip Gough and William Tunmer in 1986. In short, the simple view suggested that comprehension was the sum of a reader's oral language skill (sometimes aligned with “listening comprehension”) and ability to decode print. The simple view of reading negated the possibility of comprehension prior to decoding skill development.

More recently, several researchers are questioning the sequential assumption inherent to the simple view. Understandings that are helpful to comprehension, such as sequence, causal relationships, and inferring, can be developed through exposure to aural and visual texts prior to the development of decoding skills. The question of when comprehension begins and how to best support children's emergent comprehension is still being answered.

CONCEPTUAL FRAMEWORK FOR TEACHER PREPARATION PROGRAMS

Early childhood education (ECE) can have a profound effect on improving the lives of young children. However, too many children attend ECE programs that are mediocre at best. Increasingly, federal, state, and local policy makers have focused on developing and implementing professional development systems to prepare, train, and improve the early childhood workforce as a means of improving ECE quality. This entry examines the ways that a conceptual framework guides the structure and content of teacher preparation programs in order to help improve teachers' practices and student learning.

Main Features of a Conceptual Framework in ECE Teacher Preparation Programs

Clear Targets

Conceptual frameworks help guide the structure of teacher preparation programs by integrating and synthesizing the important lessons from the field and providing targets for professional development activities. The most effective frameworks are typically theoretically driven and empirically supported, and often they integrate key stakeholders' goals or a program's mission. With the increased economic, social, and linguistic diversity of children who attend ECE programs, conceptual frameworks also emphasize how teachers serve the individual needs of students from varying backgrounds.

Conceptual frameworks help provide a clear definition of what is expected of teachers and ensure a common language for educators, practitioners, and policy makers to talk about high-quality teaching. Teacher preparation programs are most effective when they apply conceptual frameworks that articulate the specific knowledge, skills, and processes needed to produce gains in student learning and positive social adjustment. Conceptual frameworks in ECE typically focus on both (a) content standards that provide guidelines for concrete skills or dispositions needed to teach content-focused domains (e.g., math and literacy) or basic pedagogical knowledge (e.g., understanding of child development) and (b) practice standards that highlight the processes by which teachers implement instructional practices in the actual classroom.

Aligned Professional Development Activities

Teacher preparation programs then provide activities that are directly aligned with the key skills, knowledge, and processes articulated in the conceptual framework. There are a number of ways to structure teacher preparation activities around these goals through preservice and/or in-service training programs. In particular, models in which expert coaches or veteran teachers provide constructive feedback using direct classroom observations help improve classroom quality and children's subsequent outcomes. Peer-to-peer observations also allow teachers to see other teaching practices and provide opportunities for critical reflection and feedback. Moreover, professional development programs often work toward helping teachers become leaders of their own professional development who continually seek knowledge about best practices, support each other and offer feedback, and reflect on their own teaching practices.

Monitoring and Tracking

A conceptual framework also provides a standard way of measuring teachers' strengths and weaknesses across teachers' target skills, knowledge, and practices to evaluate whether professional development activities are indeed improving

classroom quality and child outcomes. Monitoring and tracking can be used for accountability purposes as well as part of an iterative feedback loop to inform ongoing professional development efforts and refine the targets and activities of the teacher preparation programs.

Example of an ECE Professional Development Conceptual Framework

One example of a validated conceptual framework for understanding and improving teacher effectiveness is the teaching through interactions framework. The framework is based strongly in developmental theory on the importance of children's close-in environments as well as decades of empirical research on the types of exchanges between children and teachers that most strongly promote positive child development. The teaching through interactions framework organizes interactions into three broad domains: emotional support, classroom organization, and instructional support. A validated classroom observation tool, the Classroom Assessment Scoring System (CLASS), is used to systemically code the quality of teacher-child interactions in teachers' classrooms across the three domains.

Professional development activities, including coaching and coursework, are then directly tied to teachers' observed interactions in the classroom. For example, in one professional development program that applies the framework, coaches use the CLASS observation tool in teachers' classrooms to focus teachers' attention on the key interactions that best promote children's learning. Teachers' progress is monitored and tracked by coaches to provide interactive and ongoing feedback throughout the school year. Empirical evidence suggests that professional development activities using the teaching through interactions framework improve teacher practices and produce gains in children's academic and social skills.

Conclusion

A conceptual framework defines what teachers should know and do based on theory and evidence.

An aligned professional development program then provides activities that are directly related to the key competencies outlined by the conceptual framework and monitors and tracks teachers' progress over time. This type of teacher preparation and accountability system has the potential to be integrated into local, state, and federal programming and policy. Having a clearly articulated conceptual framework for ECE teacher preparation programs guides the organization and implementation of teacher preparation programs and helps ensure that the programs are effective in promoting young children's development.

CONFLICT MANAGEMENT

A conflict is an expressed disagreement between individuals. Conflicts, and interactions around them, define much of human life, every moment of every day. The term *conflict management* refers to the process of making conflicts manageable so they can be resolved civilly and cooperatively by the parties involved.

Two related terms are *conflict mediation* and *conflict resolution*. Conflict mediation refers to the leadership provided by a third party that guides parties in conflict to resolve the conflict. Conflict resolution, for the sake of this discussion, refers to a formal process of conflict mediation that typically involves application of a specific system and sometimes includes institutional involvement, such as a formalized conflict mediation service. This entry first discusses the phases of conflict management and the skills children need to develop to manage conflict. It then discusses the role of the caring adult in helping young children with conflict management.

According to Susanne Wichert, learning to manage conflicts by young children occurs in three phases: (1) *high-level mediation*, during which a third party works as an active coach to calm the conflicted parties and lead the children through the mediation process; (2) *low-level mediation*, when

children have progressed in learning calming and mediation steps and, with a leader's facilitation, take on some dynamics of the mediation themselves; (3) *child negotiation*, during which at least one child in the conflict takes leadership in the calming and negotiation processes, and the children resolve the conflict on their own.

Developmental Dynamics

An accepted goal of caregivers in relation to social-emotional development is that young children gain a psychological foundation in the cluster of skills needed to resolve problems civilly. In reality, leaders continue to work on these high-level skills their entire lives:

- Impulse control, or calming one's self enough to approach the conflict civilly
- A willingness to join with the other in solving the problem
- Perspective taking—the ability to understand a situation as the other party perceives it
- Expression of thoughts and feelings in ways that are not hurting to the other
- Positive adaptation of past experience to productively address the present situation
- Developing communication abilities that, with an adult's assistance, allow participation in the conflict mediation process

The operation some brain psychologists use to describe the utilization of this skill cluster is *executive function*. Executive function seems to begin development at about age 3 and does not operate with full developmental maturity until a person is in his or her mid-20s. Preschool children are just beginning the brain development that makes possible the affective, cognitive, social, and language skills needed for conflict management. Because of nascent executive function and a lack of social experience, young children make mistakes in behavior relative to these skills, resulting in frequent conflicts that they cannot easily resolve on their own.

Young children's stress levels have direct and continuing impact on the development of executive

function. An unmanageable stress level, termed *toxic stress* by Jack P. Shonkoff and Andrew S. Garner, causes the child to perceive even everyday situations as threatening. Perceived threat causes amygdala-driven cortisol reactions in the brain that override developing executive function and trigger survival behavior that frequently includes aggression. Aggressive, self-defensive impulses escalate conflicts and make management efforts, both mediated by the leader and initiated by the child through executive function, difficult. A meta-analysis by Megan R. Gunnar, Adriana Herrera, and Camelia E. Hostinar concluded that children who fall into a cycle of *stress–conflict–aggression–leader discipline–continued stress* face significant long-term challenges in relation to conflict management ability and long-term mental health and social relations.

The same meta-analysis determined that sustained, secure relationships with adults are essential for children to gain the trust necessary to weather missteps in learning this complex skill cluster. Positive adult guidance, through secure primary attachments with family members and secure secondary attachments with early childhood professionals, is critical for the development of the conflict management skill cluster.

Modeling and Teaching Conflict Management

The caring adult's priority, both in terms of immediate situations and broader developmental dynamics, is to help the child keep stress at manageable levels, so that conflict management skills can be learned. When intervening in pronounced conflicts, a *first step* is to calm all parties down, beginning with the adult who is intervening.

A usual calming strategy is to acknowledge each child's upset feelings and use soothing words to de-escalate the conflict. When one or both children have lost emotional control, the adult guides them in a calming process that typically includes physical distancing from the place of conflict and enough time for the children to regain composure. Separation to a quiet spot is **not** "a time out," or removal as a consequence of something the child has done. Instead, moving the child away from the

conflict is effected so that the child can become calm and mediation can occur: It is a nonpunitive *cooling down time*. The caregiver may use soothing words, physical proximity to the child, or intentional distance, whatever works to assist the individual child to calm down. Some children may need more time than the teacher might typically allow in order to become calm. For the sake of the individual child, or for general classroom management reasons, the leader may conduct the remaining steps of mediation later in the day.

A *second step* is for the leader to mediate an agreement as to how each child saw the conflict. For this step to be successful, the leader needs to be firm, friendly, and impartial. The objective is not to establish who is right and who is wrong, but to guide each child to agree about how that child *and the other child* each viewed the matter in dispute.

A *third step* is to guide the children in brainstorming possible solutions to the dilemma. Depending on language development and abilities, the leader might nudge the children into suggesting solutions themselves, or offer solutions herself or himself.

A *fourth step* is to lead the children to agree to try a solution. The leader's objective during the fourth step is to facilitate the solution all have agreed to. Often reconciliation is a part of the solution. The leader does not force an apology, which might result in conflicted feelings, but asks the children how they can each help the other to feel better. If the mediation has been successful, most children will have ideas about this.

The *fifth step* is to monitor and follow up on the solution. In relation to the immediate situation, the leader observes the children's behaviors and provides positive feedback as to their efforts. She or he talks further with the children to teach future alternative responses that would prevent conflict-escalation and possible harm. The leader especially talks with either child who used aggression during the conflict about techniques for managing impulses and strong feelings—such as summoning a leader and/or leaving the situation.

CONGRUENCE

Congruence, in the most general sense, refers to a state of agreement, correspondence, or similarity. In many areas of psychological literature and research (e.g., vocational psychology, child temperament theory), the term *congruence* is sometimes used interchangeably with *fit* and typically refers to a match between individual characteristics or values and environmental demands, which is hypothesized to influence a wide variety of psychological phenomena, including satisfaction, adaptation, motivation, engagement, commitment, and personality consistency. The term *agreement* often is used interchangeably with *congruence*.

With regard to early childhood education, practitioners and researchers have focused on the construct of congruence as it relates to school–family relationships and collaboration and have adopted a definition of congruence as the continuity or common approach among home and school contexts. Using this definition, this entry discusses how congruence affects student outcomes, reviews research supporting the importance of school–family congruence, and discusses what can be done to facilitate higher levels of congruence.

Overview and Theoretical Background

Within educational research, the past several years have yielded a growing interest in the impact that families and schools have on student performance. Urie Bronfenbrenner's ecological systems theory has become one of the most commonly used lenses through which practitioners and researchers alike view and explore students and their development over time. Bronfenbrenner's theory specifies that children and adolescents develop within a set of interrelated, interacting environmental systems (e.g., home, school, community), all of which have the capacity to exert varying degrees of positive or negative influence over an individual.

However, while much of the educational literature rooted in systems theory has focused on protective factors embedded within *either* the home or school environments, researchers are increasingly

focusing on the potential positive influence to be exerted when home *and* school work in tandem. Furthermore, in contrast to simply focusing on developing relationships (i.e., connections between families and schools and the reciprocal interactions among them over time), researchers are instead urging schools and families to strive for cultivating *partnerships*. That is, schools and families should make every effort to form a specific type of relationship characterized by two-way communication, collaborative problem solving, shared decision making and goals, and joint responsibility and accountability, all with the focus of supporting students and families in order to optimize educational outcomes. Such partnerships are not only believed to be essential to promoting positive outcomes for students but have also been posited as protective factors for children at risk of academic failure.

An increase in educational research and practice initiatives related to the establishment and maintenance of effective school–family partnerships has brought about discussion of key concepts underlying and characterizing the partnership process; among the most cited of these concepts is congruence. Often stressed in discussions of the underlying principles of healthy and effective school–family partnerships are the importance of continuity across home and school in providing consistent learning opportunities, advocating similar structure and climate within the home and school, promoting like goals and common messages about the value of learning and education, offering comparable levels of support, and modeling consistent behaviors. In addition, it has been suggested that children are more likely to commit behaviorally and socially to certain contexts when they are receiving congruent messages about values, goals, expectations, and aspirations from both the school and family environments.

From an alternate perspective, there are also numerous dangers associated with *incongruence* in school–family relationships, as students within these systems often receive conflicting messages about the importance of learning. This, in turn, can lead to higher levels of risk for negative outcomes

for those students. Although all children and adolescents experience psychosocial pressures from the various contexts in which they learn and develop, those who experience discontinuity among home, school, and peer systems tend to have the most difficulty transitioning between different contexts and, thus, are at greatest risk for poor school performance or mental health concerns.

Supporting Research

Whereas numerous empirical investigations exist reporting significant correlations between parent involvement indicators (e.g., home–school communication, parental aspirations, participation in school activities) and student success, and demonstrating the positive influence of family components in interventions aimed at changing student learning and behavior, less research has been done investigating the influence of school–family partnerships and the interactions that characterize them. Among the investigations that have focused on these variables, increased support has been found for interventions that involve *active collaboration* between parents, students, and schools, compared to those that include only a family or school component. In addition, many have noted that a key feature found in the most successful interventions is that schools and families not only collaborate with one another but also treat each other *as equals*, exhibiting mutual respect and empowerment.

Research examining consultation approaches and their effect on student outcomes has yielded similar evidence for the utility of involving parents *and* teachers in the consultation process. For example, among the various parent consultation models, the conjoint behavioral consultation model, involving consultation with both parents and teachers rather than one or the other, enjoys the strongest support for producing significant school-related outcomes. In addition, several published reviews have found that consultation services involving families, educators, and school psychologists in joint problem solving not only are highly effective in improving students' academic, social, and

behavioral functioning but also have been rated as favorable by participants in the process.

As evidenced by these studies, the influence of and rationale for schools partnering with families is well established, and scholars are increasingly calling for a shift in research focus from the question of “why” establish these partnerships, to the more process-related questions of “how” and “what works.” The previously discussed research and theoretical literature establishes the theoretical necessity and importance of collaboration, interaction, and continuity in creating and maintaining effective school–family partnerships and improving student outcomes. However, limited empirical research has been done to explore the impact these or other similar characteristics actually have on student outcomes. The studies that have looked at student outcomes found generally positive effects (e.g., gains in academic achievement), for example, when home and school environments are congruent in terms of rule systems and perceptions of student ability. In addition, some found that congruence between school and family views on education was particularly important in terms of countering information from competing sources such as students’ peers or media. Furthermore, discontinuity between families and schools has been found to compromise parents’ and teachers’ overall effectiveness as socializing agents. In general, however, additional research is needed to investigate which specific aspects of school–family congruence contribute most to positive student outcomes.

It is important to note, however, that several challenges and limitations exist in attempting to research school–family partnerships. Most evident are the inconsistencies and methodological flaws that pervade this body of literature and greatly limit the conclusions that can be drawn. For example, many studies that have looked at the success of interventions involving students’ families in some way (e.g., home component, collaborative approach) have cited methodological weaknesses such as the use of outcome measures with insufficient reliability and validity; failure to isolate effects of specific components or report participant data and effect sizes; or a

general lack of replication studies, sufficient follow-up data, and between-group design studies. Furthermore, within this area of research it is difficult to establish the direction of influence from school–family collaboration to child outcomes. These limitations impede clarification of the precise process by which school–family partnerships contribute to improved student outcomes and therefore should be taken into account when considering the previously discussed empirical findings.

Implications and Future Directions for Researchers and Practitioners

The literature discussed earlier provides a handful of important implications for both practitioners and those conducting research in the area of early childhood education. First, it makes clear the necessity for a considerable shift in focus of those in the educational field, a shift from investigating and looking to maximize school *or* family influence individually, to increasing and capitalizing on the joint influence of the school–family partnership. Furthermore, with this shift in focus comes the increased initiative to foster congruence and continuity across home and school contexts.

Although more research is needed to ascertain the specific relationship between school–family congruence in various aspects of learning and development and child outcomes, it is clear that congruence is essential to the cultivation of effective partnerships between home and school contexts, as well as the promotion of healthy development. Moreover, findings supporting this concept hold even greater weight for families and educators of students at risk for academic failure and other poor outcomes, as it seems that adequate two-way communication, collaborative problem solving, and other practices thought to promote congruence between home and school can serve a protective role in such instances.

Thus, with the importance of congruence and continuity well established, practitioners and researchers alike are tasked with determining the most effective ways of encouraging congruence

between home and school contexts. Several strategies have been suggested for achieving this goal. For example, school personnel should be encouraged to proactively establish and maintain regular, productive, two-way communication with families that emphasizes shared accountability for student outcomes. Too often, teacher–parent communications are limited to reports about a student’s academic or behavioral failures, which leads to predominantly negative interactions between family members and school personnel. Instead, those who work with students should aim to communicate with families about those students’ successes as well as their struggles, sharing responsibility for both victories and shortcomings and encouraging collaborative problem solving when conflict arises. In addition, schools should increase initiatives to garner involvement of families and communities in the educational process. This may be done through various community outreach campaigns and activities, informing and educating community members about how they can become involved in their children’s schooling and encouraging them to do so.

Lastly, as discussed earlier, the need for additional research in the area of school–family congruence is clear. Specifically, future studies should endeavor to focus on congruence in different aspects of the school–family partnership, examine the effect congruence has on various student outcomes, and investigate different methods of establishing and maintaining congruence between home and school contexts. Research such as this will not only lead to a better understanding of this complex construct and its potential for positive impact in the lives of students but also help determine what can be done to facilitate congruence between home and school contexts. Only then will schools and families be able to most effectively work together to bring about student success.

CONSTRUCTIVISM

Constructivism is a philosophy and theory describing how knowledge is acquired. In this entry, constructivism is first described in general with respect to education at the elementary, middle school, high school, and college levels. It is then discussed with respect to early childhood education because early education has its own history, especially at the kindergarten and prekindergarten levels. The emphasis in Grades 1 through 3 is on the 3 Rs, but preschool education has a long tradition of “child development” with an emphasis on play.

Many definitions of constructivism have been proposed, but the following ideas can be found in all descriptions, according to James Pelech and Gail Pieper:

- People do not discover knowledge; they build it from within.
- People create knowledge by connecting new information to their previous knowledge.
- Learning involves active restructuring of one’s thinking.
- People create new knowledge by using personal experiences and social interaction.

The term *constructivism* was first used in 1977 by A. Jon Magoon in an article he wrote for the *Review of Educational Research*. Although the term *constructivism* had not been used before 1977, philosophers such as Plato and Aristotle intuitively recognized the fact that individuals create their own knowledge by modifying their previously constructed knowledge. For example, Plato realized that human knowledge is not passively received and that we actively interpret the information received through the senses.

St. Augustine and St. Thomas Aquinas, as well as Giambattista Vico, also included constructivist ideas in their writings about learning. Both John Locke, an empiricist, and Immanuel Kant, a rationalist, stated that people construct their own ways of knowing the physical world. Among the more recent writers, constructivist ideas can be found in

the writings of John Dewey, William James, and Lev Vygotsky. Jean Piaget is the clearest example of a constructivist as can be seen in his 1954 book, *The Construction of Reality in the Child*.

Constructivism emerged in reaction to the strong influence of empiricism and behaviorism. Empiricists assume that knowledge originates outside the individual, who internalizes it through the senses. Behaviorism is a more precise, scientific theory that grew out of empiricism. Behaviorists believe in causing learning by systematically rewarding the learner for making “correct” responses.

Although constructivism is a *descriptive* theory, its *application* can be found in education in many different forms. A traditional lecture punctuated with questions and discussions by the audience is one example. Another example is cooperative groups, and a third example is problem-based instruction.

Constructivism in Early Childhood Education

Because early childhood education covers the years between birth and age 8, it is impossible to think about early childhood curricula without examining how each deals with play. There is a large variety of early childhood curricula in existence today, and one way of characterizing them is in terms of how their creators thought about play.

Another characteristic of early childhood curricula is that it has a long tradition of focusing on child development as opposed to the subject-matter approach of elementary schools. As the term *development* implies, the child development approach has constructivist elements.

The Four Types of Classrooms Described by DeVries

A way of describing constructivism in early childhood education is in terms of the four types of curricula conceptualized by Rheta DeVries. She categorized the following four types in terms of how play is incorporated in the curriculum and said that type D characterizes a constructivist approach:

Classroom Type A: Play is peripheral to learning and academic work.

Classroom Type B: Play is disguised academic work.

Classroom Type C: Play is integrated with social and emotional developmental goals.

Classroom Type D: Play and work are integrated with social, emotional, moral, and intellectual developmental goals. (DeVries, 2001, p. 82)

Types A and B are rooted in elementary education, and the emphasis is on academics. This approach reflects an empiricist or behaviorist view of knowledge, and learning is believed to result from the transmission of information from outside the individual. By contrast, types C and D share the goal of development. These have their roots in the history of early childhood education in the United States, and the curriculum stresses self-selected, self-directed activities in centers of interest such as housekeeping, blocks, sand, and water.

Classroom Type A

Children in type A classrooms spend almost the entire day in academic work, leaving little time for play. Examples of academic work include letter sounds, the days of the week and months of the year, color names, time on a clock face, and the number of cents in pictured coins.

Center time is often reserved for the last 20 or 30 minutes of the day as a reward to children who have finished their work. During this time, children may build with blocks, play with toy cars and trucks, and engage in pretend play.

Classroom Type B

In classroom type B, children also work on academics, but these are disguised by the use of colorful materials intended to appeal to children. Children in type B kindergarten classrooms may spend some time in large group activity such as listening to stories and watching informational videos on topics such as farm animals (also found in types C and D classrooms). Rather than have free choice, children typically follow a daily

or weekly rotation through the following types of centers:

Classification/math: Children may put together paper cutouts of flower pots of the same color or put cutout, numbered bees in numerical order.

Literacy: Children may put together two halves of a paper butterfly, one half with an uppercase letter and the other with its corresponding lowercase letter.

Fine motor skills/art: Children may cut out petals outlined by the teacher on construction paper.

Classroom Type C

In contrast to the focus on academics in classroom types A and B, the goal of classroom types C and D is development from within. The curriculum stresses self-selected, self-directed activities in centers of interest such as the following:

Sensory experience: Children pat and roll Play-Doh. They use funnels, pour water into different containers and empty them, and wash dolls.

Literacy: Children look at books in the library area. They listen to stories read by the teacher or to recorded stories, write or draw stories, and dictate stories to an adult.

Construction: Children build structures with blocks and Legos.

Pretend play: Children dress up as adults and pretend to cook, eat a meal, and feed a baby in the housekeeping center.

Art: Children paint at the easel.

Cooking: Children help the teacher make muffins by pouring ingredients as the teacher directs. Each child who is observing gets a chance to stir.

Classification: Children sort plastic animals by color.

Science: Children learn that fire needs air to burn by watching as the flame of a candle is extinguished when a glass is placed over the candle.

Classroom Type D

Type D classrooms look like type C classrooms on the surface, but type D teachers are constructivist and teach with a different goal in mind—autonomy as the aim of education. What Jean Piaget meant by “autonomy” is not the *right* to make decisions for oneself but the *ability* to take relevant factors into account and decide for oneself, independently of reward and punishment, what is right or wrong in the moral realm, and what is true or untrue in the intellectual realm. (Readers interested in the subject of autonomy as the aim of education are referred to Chapter 4 in the 2000 book *Young Children Reinvent Arithmetic* by Constance Kamii.) Autonomy as the aim of education is in contrast with the obedience that traditional schools inculcate.

When autonomy is the aim of education, teachers engage children in making rules to live by and in making some decisions about life in the classroom. When children make rules to live by, they have to exchange viewpoints with others and think hard before they vote.

In type D classrooms, some of the classroom activities look like child development activities, but they are conducted differently to encourage children to think and to make decisions. A few examples follow:

Musical chairs: Before playing the game, children negotiate to decide whether to play with as many chairs as children, or with one chair fewer than the number of children. They then negotiate to decide how to arrange the chairs—in a line facing the same way, back-to-back in two lines, or in a circle. If there is a dispute, the teacher facilitates the exchange of viewpoints until the parties agree on a solution.

Cooking: Two children select a recipe and decide what ingredients they need to ask the teacher to get to cook for the class snack on the next day. On the next day, they follow a written and illustrated recipe to make the class snack, without the teacher’s assistance.

Physical knowledge activities: These are activities such as pick-up sticks in which children act on

objects to produce a desired effect. In pick-up sticks, children try to pick up one stick after another without making any other stick move. A great deal of logico-mathematical thinking is stimulated when the goal is to pick up more sticks than anybody else. For example, children *classify* the sticks into “those that are touching other sticks” and “those that are *not* touching any other stick.” They *seriate* the sticks into “the easiest to try to pick up,” “the next easiest,” and “the hardest.” They make *spatial* and *temporal relationships* when a stick is resting on another stick.

Pretend play: Using a red sweater for a hood, children cooperate to act out *Little Red Riding Hood* for other children to watch.

Literacy: Children write in personal journals at the writing table, write or pretend to write stories that they illustrate, or make a list of things they did over the weekend.

Mathematics: As they play a bowling game, children figure out how to keep score on a whiteboard to know who won. They also play card games such as Piggy Bank in which they try to find two cards that make five (a 2 and a 3, for example).

A characteristic of DeVries’s type D classroom is that it is based not on a philosophy but on Piaget’s scientific theory. In *The Origins of Intelligence in Children* and *The Construction of Reality in the Child*, Piaget explains his idea that beginning on the first day of life, knowledge is constructed from within. Piaget went on to study scientifically for more than 40 years children and adolescents’ construction of logico-mathematical knowledge.

As can be seen in Figure 1, the relationship between behaviorism and Piaget’s constructivism is analogous to the one between the geocentric theory and the heliocentric theory. The geocentric theory, which states that the earth is at the center of the universe, existed first and was very limited in scope. The heliocentric theory turned the relationship between the sun and the earth upside down by stating that the sun is at the center of the universe and the earth and planets revolve around it; this theory greatly expanded our view of the

Figure 1 The Relationships Between Behaviorism and Piaget's Constructivism and Between the Geocentric and Heliocentric Theories

universe. Likewise, behaviorism existed first and was (and still is) limited in scope to surface behavior. Piaget's constructivism went beyond surface behavior and expanded the scope of learning.

Behaviorism and Piaget's constructivism are both scientific theories that have been verified all over the world. The question that must be answered is: How can two scientific theories be so contradictory and both have explanatory power? The answer to this question is that Piaget's theory can explain everything behaviorism can explain, but the converse is not true. As a biologist, Piaget pointed out that all animals adapt to reward and punishment and that higher animals such as dogs can anticipate the reward and punishment. Dogs can anticipate the appearance of meat when they hear a bell. Piaget also explained the concept of "extinction" by stating that when the meat stops appearing, dogs stop anticipating its appearance.

An interesting fact about these scientific revolutions is that the new theory supersedes the old one, but the old theory continues to be used within a limited scope. For example, the sun stopped going around the earth when the heliocentric theory was introduced, but we still speak about the sunrise and sunset, and the weather forecast continues to tell us that the sun rises every day. Likewise, Piaget's constructivism has been verified all over

the world, but it is still true that behaviorism produces more correct answers to specific questions.

Some early childhood curricula claim to be based on Piaget's constructivism, but they are not because they fail to deal correctly with logico-mathematical knowledge. Logico-mathematical knowledge consists of mental relationships that are constructed from the first day of life and include classificatory, seriation, numerical, spatial, and temporal relationships. Other curricula claim to be constructivist, but they are based on intuitive feelings that do not have a scientific foundation.

Since the 1960s, preschool education has focused heavily on the school readiness of disadvantaged children. In trying to promote children's linguistic and intellectual development, child development teachers often use behaviorist theory without realizing the contradiction. A heavy emphasis on testing has also caused the National Association for the Education of Young Children to include more specific cognitive and linguistic objectives in its recommendations on developmentally appropriate practice.

Constructivist Programs in Grades 1–3

Reading, writing, and arithmetic become the major focus of the curriculum in Grades 1 through 3. In reading and writing, the whole language movement, which supports teaching children to read through literature and focus on the meaning of words, grew out of opposition to associationist and behaviorist practices. Some of the leaders of the whole language approach saw in research by Emilia Ferreiro and Ana Teberosky, based on Piaget's theory, a scientific rationale for whole language. Books such as *How Children Construct Literacy* and *Early Literacy: A Constructivist Foundation for Whole Language* explain further the connection between whole language and constructivism.

In arithmetic, too, constructivist mathematics developed, especially in California, on the basis of an intuitive conviction that traditional math was not working. As can be seen in her book *Young Children Reinvent Arithmetic*, Kamii's approach to constructivist mathematics was different in that her approach was based on Piaget's theory. She

hypothesized that children should be able to invent arithmetic without any teaching in the traditional sense. This hypothesis was not only confirmed, but the teaching of “carrying” and “borrowing” turned out to be harmful to children’s development of number sense and understanding of place value.

CONSTRUCTIVIST CURRICULUM

Constructivist curriculum is a framework for planning and implementing activities, creating the physical environment, creating the social environment and classroom culture, and defining the role of the teacher. This curriculum framework is based on the theory of learning called constructivism. This entry first discusses the theoretical basis of constructivist curriculum and then the overarching values and principles of the constructivist curriculum. Then, each of these elements of a curriculum framework is discussed: (a) activities and experiences planned and implemented for children, (b) creation of the physical environment, (c) creation of a classroom culture, and (d) role of the teacher.

Constructivism

Constructivism is a theory of how children learn, derived primarily from the work of the psychologist Jean Piaget. This theory contends that children learn through interactions with their environment, constructing knowledge through those interactions. Children bring to these interactions their mental schemes, concepts, or “theories,” based on their prior experiences and constructed learning. By applying these theories, children encounter new knowledge that is then incorporated in more and more complex understanding of the world. The term *theory building* is used here to refer to this process of knowledge construction. Although constructivism focuses on the cognitive processes that occur as children interact with the world, these processes are seen as closely connected to the social and emotional

domains, acknowledging the importance of motivation and relationships.

Lev Vygotsky, a Russian psychologist, also has contributed to the theoretical framework that underlies constructivist curriculum. His work is the basis of social constructivism, focusing more on the role of the social context—adults, peers, and language—in the construction of knowledge.

From the perspective of constructivist theory, children are, from birth, striving to understand the world around them, actively applying their theories and learning from those interactions. The social and physical environment is critical for providing opportunities for knowledge construction, but it is not the source of children's learning. This is in contrast to behaviorist theory, which contends that it is environmental stimuli and external reinforcements that produce behavioral change, with less focus on biological cognitive structures that are the central to the constructivist approach to learning.

Elements of the Curriculum Framework

Constructivist curriculum has been articulated by many, with differing foci, and is seen as a core element of many approaches, including the work in and inspired by Reggio Emilia and the project approach. Although there are a number of different curriculum frameworks that fall under this category, there are some shared principles and values underlying them. One shared value is a deep respect for children and what each child brings to the learning context, acknowledging and celebrating diversity of experiences and perspectives. Underlying constructivist curriculum is an image of the child as capable and competent, with openness to learning from and with children. Thus, another belief is that teaching involves actively supporting and facilitating the child's learning rather than transmitting knowledge; in fact, constructivist curriculum includes the view that teachers are co-learners and co-researchers with children. Broadly, another view underlying constructivist curriculum is that the aim of education is not the accrual of information but the ability to think deeply and critically and to engage in collaborative and respectful work with others.

Another commonality is the consideration of the different kinds of knowledge that children construct and acquire. First discussed by Piaget, but elaborated on by Constance Kamii in terms of early childhood education, is the delineation of three types of knowledge—physical knowledge, logico-mathematical knowledge, and social (or arbitrary) knowledge. Physical knowledge is empirical and observable; logico-mathematical knowledge is in one's head and is applied to the empirical world (e.g., size, which does not exist in the object but depends on what one is comparing); and social/arbitrary knowledge. The first two, physical and logico-mathematical knowledge, are constructed by the child through interaction with the world. The third, social knowledge, cannot be constructed and must be transmitted to the child, as, for example, the particular names of things or practices unique to the child's culture.

Among the many approaches to constructivist curriculum, the work of Kamii has been a cornerstone of such efforts. In her early work, she (with Rheta DeVries) focused on physical knowledge activities and games with rules; in her later work, she has focused on mathematics, from preschool through fourth grade. She has also contributed a deeper understanding of Piaget's theory to include a focus on autonomy as the aim of education.

Activities and Experiences

In thinking about curriculum in general, there is a continuum between child-directed and teacher-directed activities and experiences. Whereas there are some in the field who might contend that constructivism falls on the child-directed end of the continuum, others consider this a common misconception. Constructivist curriculum entails a dynamic interaction between the teachers and the children, a negotiated "dance" that honors children's interest and engagement and that is both provocative and responsive. Teachers are observant and reflective, often basing planned activities on what has been observed in previous experiences or on spontaneous opportunities.

A few key elements are characteristic of the activities and experiences representing a constructivist curriculum. In general, children have opportunities to interact with the materials and the experience in a number of different ways, allowing for different points of entry for each child. As children engage, they are free to pose their own problems and questions of the materials and be self-directed. The opportunity in the experience is clear and requires little (or no) explanation by the teacher, although often an introduction is offered that is nondirective but could include discussion of any issues for children to consider when engaged (e.g., safety issues).

Activities and experiences can be more or less structured, depending on the teachers' intentions. For example, for an experience that involves combining cornstarch and water, creating an interesting liquid/solid substance, there might or might not be other materials available for further combinations, depending on whether the teacher is interested in how those materials interact with the mixture of cornstarch and water. An experience rolling balls down ramps with different textures might or might not also provide the opportunity for children to vary the height of the ramp or the size of the ball. Teachers' planning considers whether the intent is to explore a range of possibilities or to narrow the focus on fewer.

Regardless, the planning of activities, while thoughtful, thorough, and intentional, is combined with flexibility, with the willingness to change direction based on the teachers' observations of children's actions and interests. This combination of planning and flexibility is a hallmark of a constructivist approach to experiences and activities.

Creating the Physical Environment

The physical environment is an essential part of the constructivist curriculum. Intentionally designed to support children's explorations and experimentation, the environment is designed to allow for unmonitored movement and good flow throughout the spaces. Flexibility is another key element of the environment, as the space needs to

be adaptable to different uses and thus easily transformable. Contrast this with a more traditional curriculum approach, with individual desks facing the front of the room, implying whole group work with the teacher directing. In addition, materials in the space should be displayed intentionally to encourage the children's work and play, with accessibility to those materials children might choose to incorporate into their play.

Materials and objects are chosen carefully, with an eye to multiple possibilities of their use rather than constrained choices. Because deep engagement is valued, the materials and objects are available over a period of time rather than rotated or changed constantly.

Thinking about the physical environment also includes ensuring that it supports the classroom culture that is a part of the curriculum.

Creating a Classroom Culture

The social environment is also a key element of the constructivist curriculum. Two aspects of the social environment that are intentionally planned and monitored are (1) social interactions in the classroom and (2) values and constraints that provide guidelines for the classroom community.

The constructivist curriculum incorporates opportunities for both individual work and social interaction. Young children are social beings, and they learn a great deal through and about social interactions with peers as well as with adults. Setting up activities that have opportunities for either working alone or with peers is considered, as are activities where social interaction is necessary. In addition, the constructivist curriculum will incorporate opportunities for whole group discussions in which children have the opportunities to listen and respond to multiple perspectives.

The values and constraints, or guidelines for the class, are both explicit and implicit. Explicitly, many constructivist teachers work with the children to develop classroom rules that will enable them to work together, including ideas for handling conflicts and problems as they arise. Implicitly, the constructivist curriculum implies a culture of respect and

caring, which can be stated, practiced, and modeled in many contexts and supported in many ways.

The Role of the Teacher

The constructivist teacher plays a very dynamic role in the classroom. First, the teacher models engagement, inquiry, and respect for others in how ideas are presented to the class, in how activities are described, and in how classroom discussions are held. The teacher is creating a rich, supportive, physical and social environment. The teacher is an active observer, deeply observing what children are doing and listening to their conversations. The teacher is a question-asker and problem-poser, basing these on observations of what is going on and being careful not to interrupt children's theory building. The teacher documents children's explorations, researching what children are doing and trying to understand what they are thinking. Finally, the teacher is a theory builder alongside the children, open to new ideas, experimenting with the curriculum, and then learning from those experimentations.

Conclusion

In sum, constructivist curriculum, grounded in the theoretical perspectives of Piaget and Vygotsky, entails a broad and complex view of curriculum—creating the physical and social environment, blending thoughtful and extensive planning with flexibility based on careful observations of children, engaging in dialogue and collaboration, co-learning and co-researching, between and among the children and teachers.

CONTENT KNOWLEDGE

Content knowledge is often thought to be the factual knowledge people learn as they study a range of academic disciplines in school. This view is, in part, true. A 2009 position statement by the National Association for the Education of Young Children (NAEYC) indicates that in addition to facts, content knowledge includes an understanding of the essential concepts, inquiry tools, and structure of various content areas, including academic disciplines. Further, NAEYC advocates that the content of early childhood curriculum should focus on language and literacy, the arts, mathematics, science, social studies, and physical activity.

In the context of early childhood education (ECE), it is nearly impossible to separate development and learning. Thus, content knowledge must also be situated and considered developmentally. This entry begins by addressing the question of why building content knowledge in the early childhood years is so important. Next, the entry further defines the three distinct elements of content knowledge (essential concepts, inquiry tools, and structure of content areas) and concludes with examples illustrating intersections between content knowledge and developmental understandings.

Why Is Building Content Knowledge in ECE Important?

The early childhood years lay an important foundation for later learning. Thus learning experiences with the youngest children should be designed to support later academic skills and success. Young children tend not to separate learning experiences into academic categories or disciplines; however, it is important that teachers of young children be aware of how learning experiences align with academic disciplines. For example, teachers of young children should be able to make connections between their curriculum and relevant aspects of each subject area (language and literacy, the arts, mathematics, science, and social studies) that is essential to children's later academic success and developing competence.

It is within the early years that children should develop confidence in themselves as not just learners but also young literary critics and authors, young artists, young mathematicians, young scientists, and young historians, economists, anthropologists, and geographers. Because children learn by doing and through active engagement, it is essential that teachers of young children model engagement in challenging subject matter as a way of building children's confidence and competence.

To model this engagement for children, ECE teachers need to possess their own rich content knowledge that extends beyond factual knowledge. In addition to possessing sufficient content knowledge, teachers of young children must also have an understanding of early learning standards and other subject matter specific standards. Effective use of sound developmentally appropriate standards along with sufficient content knowledge enables teachers to design and implement curricula that support children's content learning. A challenging curriculum emerges when there is alignment between learning standards, a teacher's content knowledge, and the teacher's developmental knowledge. An application of such knowledge informs the creation of learning experiences that focus on key aspects of each content area in ways that are tailored to the developmental needs and

constraints of a particular age group. When early subject matter learning is grounded in the essential concepts, includes inquiry tools, and reflects the structure of academic disciplines, young learners are well prepared for later academic success.

Elements of Content Knowledge

Every academic discipline is comprised of a body of factual knowledge. For example, factual knowledge includes statements such as "Plants and animals are both living things" and " $3 + 2 = 5$." However, true understanding is more than an accumulation of bits of factual knowledge; it requires that isolated bits of factual knowledge be organized and connected to one another. An understanding and application of the essential concepts, inquiry tools, and the structure of academic disciplines helps one build or construct his or her content knowledge.

The understandings one has about the structure of academic disciplines provide a framework for making sense of the overall purposes and goals of the discipline. Given that one learns content knowledge for real life and not solely for school, it is important to understand why it is that individuals learn or study particular disciplines in the first place. Science provides a way of explaining the natural world. History and anthropology seek to explain changes in the social world over time through a lens of economics, culture, or politics. Geography helps us understand how the natural world and social world interact and influence one another. Mathematics makes use of patterns and structure to create models that help us study, understand, and explain the complexities of the natural and social world. Finally, literacy—being able to read, write, and communicate through speaking, gesturing, or representing ideas in other ways—allows one to interact with the world around him or her so that it can be understood scientifically, historically, geographically, mathematically, and even poetically or literarily.

Understanding the nature of academic disciplines requires one to recognize that what is broadly accepted as factual knowledge is often subject to change. For example, as astrophysicists

refine and dispute the definition of a planet, there is contemporary debate over whether or not Pluto is a planet or what is now called a dwarf planet. As historians seek to describe and explain the past, they do so by drawing on the artifacts that have survived through the ages, all the while knowing that the surviving artifacts may or may not fully capture the realities of a past time or that at some future date new evidence might be found that challenges current historical explanations. Although one may learn key features of a persuasive argument, writers and orators apply these features in quite varied ways, and what one person finds to be a compelling argument others might very well reject.

There is a range of inquiry tools, skills, or processes that characterize the ways in which geographers, historians, literary critics, mathematicians, scientists, and writers conduct their work. This includes the ways that they generate new knowledge, make new discoveries, or engage in new ways of thinking as they work to solve complex problems. The processes are fairly similar across disciplines. For example, scientists, historians, and mathematicians all ask questions and define problems; plan and carry out ways to seek answers to their questions; gather, analyze, and interpret information; construct explanations regarding their questions or propose solutions for the identified problems; support their explanations or solutions by using evidence; and communicate their findings through a form of disciplinary argument. Writers engage in the writing process with parallels to the activities just described—they write with purpose for a particular audience, and initial drafts are critiqued and revised before final publication. One should not learn or use these tools in isolation but rather while one engages in the essential concepts that characterize each discipline.

Within each academic discipline there are essential concepts, those big ideas that help people make sense of their experiences in the world and that help them make sense of seemingly isolated facts. By their very nature, essential concepts help individuals connect ideas and support the generalizable understandings that have relevance in new

situations and even across academic disciplines. Essential concepts are foundational to academic disciplines, and yet because they are so foundational, even young children are able to access these concepts in simplified form. For example, patterns (one of the crosscutting concepts identified in the Next Generation Science Standards) abound in science (as well as many other academic disciplines). Looking for and recognizing patterns enable one to organize and classify things in the natural world. This may be as complex as recognizing the patterns of base-pairs in DNA and the three-dimensional structure of a protein that a particular sequence of DNA might produce. Recognizing patterns also helps an individual distinguish between one type of living thing and another, whether he or she is trying to distinguish between a house finch and a purple finch, a reptile and an amphibian, or simply something that is living versus nonliving. It may also be as simple as children being able to sort a set of objects based on size (or some other feature), function, or material the objects are made of. An understanding of the essential concepts within an academic discipline helps one understand the discipline in a coherent and connected way. Ideally, individuals actively construct this understanding as they make use of inquiry tools.

Intersections Between Content Knowledge and Developmental Understanding

As stated earlier, in ECE it is difficult to separate development and learning. Because of this, teachers of young children must have specialized content knowledge that some have called pedagogical content knowledge and others have called content knowledge for teaching. This kind of specialized content knowledge enables teachers of young children to transform their content knowledge in ways that make the essential concepts, inquiry tools, and structure of the discipline accessible to young children. This allows children to engage in learning content knowledge in meaningful and appropriate ways. Brief examples from literacy, mathematics, science, and social studies illustrate how a teacher's

content knowledge and developmental understandings intersect in important ways.

Long before children write with conventionally recognizable letters, their drawing is distinguishable from their writing. Initially children will convey meaning primarily through their drawings. Then they begin using random strings of letters to convey meaning with both letters and images. Random strings of letters are then replaced with “words” where there is a discernible letter–sound connection, making this emergent writing “readable” by others. Understanding this developmental writing continuum helps teachers encourage children to convey meaning through drawing and text as they recognize children’s early yet unconventional writing.

Even the simplest mathematical calculations require an understanding of numbers. An intuitive number sense begins at an early age. Counting small groups of objects helps children develop number words in sequence and ideas about quantity (the 1:1 correspondence between each number and each item). It is not uncommon for children to count before they understand quantity and for children to understand quantity before they recognize that the symbol “3” represents the quantity 3. The simple equation $3 + 2 = 5$ becomes a good deal more complex when one realizes that solving it requires the coordinated understanding of number words, quantity, and number (and mathematical) symbols.

Adults easily recognize that both plants and animals are living things, but for young children it is not uncommon for them to have difficulty understanding that plants are indeed living things. All living things grow, move, reproduce, use energy, and eventually die. Children’s developing ideas about the world, though, are largely tied to the things that they can see. Of the abbreviated list of characteristics of living things just stated, movement is the most easily observed feature and this influences what children consider to be living or nonliving things. When teachers connect this developmental knowledge with content knowledge, they are able to understand why young children often consider plants to be nonliving things and why they might also consider clouds, fire, or rivers to be living.

Chronology, or understanding the sequence of important historical events, is at the heart of knowing history. Dates and the passage of time, whether months or centuries, are abstract concepts that are difficult for young children to understand. However, even young children are able to look at a set of images or artifacts and place them in a fairly accurate sequence based on time. Recognizing the ability to sequence events as a foundational element of chronological thinking positions teachers to leverage this developmental understanding to support children’s historical content knowledge by initially focusing on sequencing events rather than dating events.

In summary, content knowledge includes an understanding of essential concepts, knowledge of and ability to use the tools of disciplinary inquiry, and an understanding of the structure and nature of different academic disciplines. When viewed in this way, content knowledge is robust, generative, usable, and readily applied in everyday situations.

CONVERGENT AND DIVERGENT THINKING

The distinction between convergent and divergent thinking has now been used in the social and behavioral sciences for more than 60 years. It has proven to be enormously useful for both theory and practice. Tests of divergent thinking can be given to children even before they start school, thus providing an early measure of the potential for creative thinking. Tests of divergent thinking have demonstrated long-term predictive validity. Empirical results indicate that the results of these tests are more strongly related to accomplishments in the natural environment than are scores from measures of convergent thinking, including the IQ and grade point average. Adaptive behavior in the natural environment requires both convergent and divergent thinking, but the latter has received a great deal of attention because of the information it provides about creative potential. This entry discusses the differences between convergent and divergent thinking, research into convergent and divergent thinking, the tests used to measure these types of thinking, and how these types of thinking relate to creative behavior and problem solving.

Divergent thinking is used for open-ended or ill-defined tasks. These allow thinking that moves in divergent directions. This allows the individual to discover original ideas. Original ideas are those that are infrequent, novel, and uncommon. Few people think of them; they are unconventional. Tests of convergent thinking, in contrast, require that an individual produce a correct or, at the very least, a conventional answer. Conventional answers are common; many people will think of the same

thing. They are in that sense unoriginal. They are often based in fact and found by searching long-term memory and drawing from experience.

The distinction between convergent and divergent thinking may imply a dichotomy, but in actuality convergent thinking and divergent thinking represent two poles on a continuum. Most tasks assessing convergent or divergent thinking actually represent one position on that continuum. Some tasks are more convergent than others, and some are more divergent than others. This is an important point, especially because realistic theories of creativity recognize that both divergent and convergent types of thinking are involved.

Research on Convergent and Divergent Thinking

The distinction between convergent and divergent thinking has proven to be especially useful for the research on creativity and for decisions about how education might support the development of creative capacities. That is because divergent thinking tests provide reliable information about originality, and originality is a prerequisite for creativity.

It was the recognition that convergent thinking and divergent thinking could be separated from one another that pushed studies of creativity forward more than any other theory, concept, or measure. Before this distinction was offered by J. P. Guilford, many people questioned whether or not creativity was separate from general intelligence. Before Guilford's work, people often thought that creativity was just a kind of intelligence, and therefore all you had to do to support creativity was to support general intelligence. Since Guilford's time, an enormous amount of research has supported the distinction between convergent and divergent thinking and further supported the idea that it is one thing to support convergent thinking but quite another to support creative potential.

Tests of divergent thinking are not tests of *creativity*. Rather, tests of divergent thinking are estimates of the *potential* for creative thinking. They are *estimates* because, like all tests, they are just samples of a larger universe of behaviors. Like all

tests, tests of divergent thinking have some measurement error. Tests of divergent thinking indicate the potential for creative thinking because there is never any guarantee that what is found on a test will manifest itself later, in the natural environment. It is not actual creative behavior that is being measured by tests of divergent thinking. It is instead a capacity that might in the future lead to actual creative behavior. Correlations between divergent thinking and actual creative behavior indicate that, when a child earns a high score on a test of divergent thinking, he or she is likely to display creative behavior.

Tests of Convergent and Divergent Thinking in Early Childhood

Many tests of convergent and divergent thinking can be used in early childhood, although with children younger than 3 years of age it is best to administer the divergent thinking tasks in an interview sort of format. This requires that the examiner have good rapport with the child. Plenty of research has demonstrated that if rapport is lacking, the divergent thinking scores will not be meaningful. Divergent thinking tests are especially sensitive to administration factors, more so than other tests of potential. The testing setting and the general climate in which a test is given are extremely important. The test setting should allow the child to relax and recognize that there are no risks, no possibility of criticism or penalty. Put briefly, divergent thinking is only accurately assessed in a *game-like testing environment* and not in a *test-like environment*.

All tests of divergent thinking work best if the child is allowed to approach them more as a game than a test. When working with children in the early elementary years, it is best if the examiner comes right out and says, "This is not a test." If a child receives a divergent thinking task but assumes that it is a test, he or she is very likely to think convergently and in a conventional fashion and not be original. Here are some of the key points to emphasize when administering a test of divergent thinking:

This is a game (not a test).

Take your time. Take as much time as you need.

There are no points being given. No grades.

Spelling does not matter (if it is a written test and not an interview).

There are no wrong answers.

The more ideas you can think of, the better!

Have fun.

Many of these are only necessary if the child has started school and thus has experienced academic tests. Preschool children also should receive divergent thinking tasks in a relaxed environment and be told to have fun and to give as many ideas as they can.

When working with a child of age 3 or younger, instead of some paper-and-pencil task, it is best to allow a child to play with a series of concrete, tangible, three-dimensional (3D) objects. These might be simple pieces of Styrofoam. The test would involve giving the child one Styrofoam shape, allowing him or her to look at it and hold it, and asking the child: "What could that be? Can you tell me all of the different things that could be?" The child should also be told to name as many different things as possible.

Good tests are reliable, and reliability benefits from having multiple items. A short test is usually unreliable. For this reason, after the child gives as many ideas as he or she can for that first 3D object, the examiner can say, "I have another fun object for you to play with," and replace the first object with a second shape. The examiner then goes through the encouragement to elicit a large number of ideas once again. After this, a third object should be used. Three objects tend to work well. Even more objects might increase the sample of ideas and might increase reliability, but it is also possible that the child will tire. *Fatigue effects* should be avoided.

Tests in the Guilford, Torrance, and Runco divergent thinking batteries all include a test called "Uses." It names a common object (e.g., spoon,

shoelace, chopstick) and asks that child give as many possible uses as he or she can think of. “Titles” is another reliable test. It names a story with which the child is familiar (e.g., Titanic, the Hobbit, Spiderman) and asks for a list of alternative titles. This is probably better for children at age 5 or perhaps a bit older. Some tests are “visual” or “figural.” They present an abstract drawing to the child and ask for a list of “all of the things this could be.”

Tests of divergent thinking are typically scored for fluency (the number of ideas given by any one child), originality (the number of unique or uncommon ideas), and flexibility (the number of conceptual categories suggested by a child’s entire output of ideas). Occasionally only fluency is used, which is justified by the correlations among fluency and the other two indices, but a careful reading of the research indicates that it is much better to consider all three indices. There is unique variance to originality and flexibility, for example, and experimental demonstrations of the independence of the three indices. The theory of divergent thinking clearly indicates that fluency alone is inadequate. Recall also that it is originality, not fluency, that is recognized in theories of creativity. The use of fluency alone should be avoided.

New technologies allow computer scoring of fluency, flexibility, and originality. They have also added indices that indicate average response latency (time between ideas) and semantic richness. It is useful to consider how each index is derived: A child’s fluency score represents the number of ideas produced. Hence, fluency is derived simply by counting the number of discrete ideas. To derive originality, the ideas given by children are listed in a lexicon, alphabetically arranged. The lexicon should also contain some indication of which child gave which ideas. Common ideas will be obvious in the lexicon because several children will have given the common ones, but only one child (or very few) will have given the original ideas. Suppose, for example, that children are asked to “list things that are square.” If one child gave “my dad’s music” as an answer, that would earn one originality point because only one child gave the idea. If 10 children gave “TV” as an

answer, they would not earn originality for that idea. It is a common idea. There are alternative scoring systems for originality, some giving weights that decrease as the commonness of the idea increases.

Flexibility is also a very important part of divergent thinking. Describing a child’s thinking as flexible indicates that the child uses a number of different conceptual categories when solving problems or generating ideas. If one child looks at that square object and says “television, computer, radio, and DVD,” these ideas are all in the electronic category and there is very little flexibility. But if the child says “television, a sugar cube, my friend’s head, and dice,” three or even four conceptual categories are used, implying a higher level of flexibility.

It can be useful to give realistic tests of divergent thinking to children in the elementary grades. Instead of asking for ideas about an ambiguous figure, for example, or ideas about square things or uses for a shoelace, older children can be given a scenario, something that could actually occur (e.g., “You are on your way to school but forgot your homework.”). Such realistic tests seem to have superior predictive validity, but there is also some indication that they are more experientially biased than the more traditional and abstract divergent thinking tasks, such as uses for a shoelace. Apparently, when children receive highly realistic tasks, they tend to draw more on memory and experience. They are not, then, using as much of their imagination or capacity for creative thinking. The use of experience is considered a *bias* because it would give children who have richer experiences an advantage. In that light, the more traditional and abstract tests of divergent thinking, which require more on-the-spot problem solving and imagination, are probably more attractive.

Convergent and Divergent Thinking in Context

It is easy to see the difference between questions designed to elicit convergent thinking versus those designed to elicit divergent thinking. The former are closed, with one or very few correct

or conventional answers, and the latter are open-ended and allow multiple responses. It is also easy to see why tests of divergent thinking are often used as estimates of the potential for creative problem solving. They are not tests of creativity per se but may be indicative of one part of creativity, that is, the production of ideas. This is especially true for the originality index from divergent thinking.

There are different kinds of divergent thinking tasks. Some are more useful with preschool children, whereas others may be useful with children entering the school years. All of them require that the child is assessed in a relaxed, game-like, playful environment. All of them offer information about a child's fluency, originality, and flexibility with ideas.

Both convergent and divergent thinking are important. Creative performance in the natural environment probably requires both convergent and divergent thinking. They may work together, or they may work in some sort of sequence, when some divergent thinking is needed, but after a time convergence becomes more important. Some performances, both in school and in the natural environment, may require one or the other rather than both. Children should have opportunities to practice both divergent and convergent thinking if they are to develop mature, adaptive problem-solving skills.

COOPERATING TEACHERS

A *cooperating teacher* is an experienced classroom teacher who serves as a mentor and supervisor to a preservice teacher who is placed in his or her classroom to fulfill a required field-based component of his or her teacher preparation program. Educational research has repeatedly confirmed that cooperating teachers play a critical role in preservice teacher preparation. This entry provides a description of cooperating teachers' roles and responsibilities, highlights the important influence that cooperating teachers have on preservice teacher development, and presents the issue of preparing cooperating teachers for their work with preservice teachers.

Overview

Clinical experiences are a central feature of early childhood teacher preparation programs in the United States. During these field-based experiences, preservice teachers have the opportunity to observe, develop, and practice critical teaching skills under the guidance of an experienced cooperating teacher. Cooperating teachers, in partnership with institutions of higher education, invite preservice teachers into their classrooms with the goal of helping them develop the knowledge, skills, and dispositions necessary to be effective teachers. In some teacher preparation programs, cooperating teachers may also be referred to as coaching teachers, mentor teachers, or co-teachers.

Cooperating Teachers' Roles and Responsibilities

Cooperating teachers play multiple and varied roles. Not only do they model skills associated with teaching, but they provide guidance to preservice teachers by explaining the decisions behind their teaching, making explicit the reasons they chose to employ specific methods and strategies. In addition, cooperating teachers scaffold preservice teachers as they engage in teaching activities such

as lesson planning, classroom guidance and discipline, and engaging with families. Cooperating teachers may also guide preservice teachers through the processes of self-assessment and reflection while offering feedback that highlights their strengths and identifies areas for improvement.

Typically, cooperating teachers also have the responsibility of conducting a variety of assessments and evaluations that are mandated by the teacher preparation institution and/or the state's licensure granting agency. Some scholars have raised concerns, however, about whether a cooperating teacher can fully achieve a true mentoring relationship with a preservice teacher in light of the power differential inherent in the evaluation process. Often, cooperating teachers work with university-based supervisors, in what is commonly called the triad approach, to evaluate preservice teachers' progress, providing both formative and summative evaluative feedback.

Recently, there has been an increase in the implementation of co-teaching as a clinical model within teacher preparation programs. This model places more of an emphasis on shared leadership between the cooperating teacher and preservice teacher than does the aforementioned triad approach. There are several potential ways to implement co-teaching, each of which places the cooperating teacher and preservice teacher in different roles at different times.

The Importance of Cooperating Teachers

Research on preservice teacher preparation highlights the powerful impact that cooperating teachers can have on the development of preservice teachers. In fact, some scholars in the field of teacher education have described cooperating teachers as perhaps the most influential component of the teacher preparation process. Studies have illustrated that cooperating teachers influence not only the preservice teachers' developing knowledge and skills surrounding teaching but also the preservice teachers' attitudes and dispositions toward teaching. With this agreement regarding

the powerful impact that cooperating teachers have on teacher training comes a call for a closer examination of the practices and characteristics of cooperating teachers that will ensure that this influence leads to the development of knowledge, skills, and dispositions that contribute to effective teaching. Concerns exist related to the potential impact of cooperating teachers who are inexperienced, unprepared, or unsupported to serve as positive mentors to teachers-in-training.

Preparing and Supporting Cooperating Teachers

Even though there is consistent evidence regarding the importance of cooperating teachers within the teacher preparation process, literature documents a surprising lack of preparation and support provided to cooperating teachers. Although many agree that cooperating teachers should be regarded as important teacher educators, few institutions of higher education are able to invest the time or resources necessary to fully prepare cooperating teachers for their important role.

Studies indicate that the majority of professional development experiences provided to cooperating teachers focus primarily on the logistics of the clinical experience, such as timelines, schedules, and completing required forms and evaluations. Most agree that being an effective cooperating teacher requires different skills than those required to be a successful teacher of young children, and yet few teacher preparation programs provide professional development experiences that facilitate the development of skills needed by cooperating teachers to be successful in this role. The issue becomes even more complex as there is little consensus regarding the characteristics, qualifications, and skills required of effective cooperating teachers. Further, many studies indicate that cooperating teachers receive little ongoing support throughout the time that preservice teachers are placed in their classrooms. Experts in the field of early childhood teacher preparation call for increased attention to this matter, and some have developed and implemented more comprehensive professional development

programs in support of cooperating teachers. Many of these programs focus on helping cooperating teachers develop effective mentoring skills such as developing relationships with preservice teachers, active listening, providing feedback, and facilitating critical reflection.

COOPERATIVE LEARNING

Cooperative learning is an interactive, structured strategy used to group all levels of children in order to meet instructional goals. Rather than working independently, children are expected to work together to complete a task. Cooperative learning groups can be used in any content area. This approach can be built into a unit of study for many purposes and at any time. It is an instructional tool designed for a specific purpose; it is not a separate program. This entry discusses the reasons for using cooperative learning and the benefits and drawbacks of the approach.

An important workplace skill in the 21st century is the ability to work together. In cooperative learning groups, children learn to work with others toward a goal. They might discover that the finished product is a better representation of the task as compared to what could be completed by each child independently. This becomes an important lesson in interdependence. The child who draws well can illustrate a product, and the child who has understanding of language can insert sounds or words to describe the product.

This approach has both social and academic benefits. Cooperative learning groups may increase self-esteem, empathy, and responsibility in all children involved in the activity. Children learn to value and appreciate individual differences. They get to interact with many other children. Various cooperative learning structures used in a classroom provide opportunities for children to get to know other children better and begin to create relationships.

Academically, groups may be effective in helping children to acquire higher level thinking skills. More children are engaged in instruction using cooperative learning; therefore, the level of understanding, the amount of time on task, and academic achievement increase. Children begin to feel comfortable expressing their ideas and opinions. They observe a range of reasoning skills and perspectives. Brain-based learning reinforces that the child must be actively involved and doing something with the information in order to learn it. Children become more self-confident as learners, develop oral language skills, and scaffold their learning through conversation and visual organizers.

Spencer Kagan has been credited with designing specific cooperative learning structures. The structure or method of cooperative learning employed depends on the outcome the teacher hopes to achieve. A few of the strategies that teachers can use are jigsaw, numbered heads together, think-pair-share, or inside-outside circle. These specific strategies have different objectives and structures for the classroom. Potential roles in these structures may also vary depending on the objective of the lesson.

Cooperative learning groups can take many forms. The key idea for the group is for children to

move from receiving information to creating knowledge within the group. It is important that all children are accountable for the end product and are able to participate in the work equally. Groups typically average from two to six children with the ideal number being four. Children may be placed in groups randomly or assigned to a specific group based on the criteria of the task.

Within these groups, children might be assigned roles such as recorder, illustrator, or reporter. Each role must be modeled and practiced for children to become comfortable with the expectations. Teachers who rush the process or do not allow enough time to practice the roles may become frustrated by the experience and not wish to continue using this instructional approach. Initially, the teacher establishes the group and the tasks. As groups work, teachers become facilitators or guides to monitor progress and learning. As children become more proficient, the teacher can provide less direct support.

It is important for the teacher to dedicate sufficient time for children to become comfortable with the idea of working together toward a common goal. Children in this new situation should receive scaffolding from another peer or adult, to continually increase and develop new skills. A child who is shy or inhibited might be more communicative in a cooperative learning group but, conversely, could also lack the social competence to be able to work effectively as part of a group. It may be necessary to provide the support of an adult. A child who has the potential to be aggressive or forceful may need coaching in better ways to interact as a group member.

Once the children have learned the roles and procedures, a benefit for the teacher is that the strategies or structures can be used repeatedly in many content areas. Practice of new content can be distributed throughout a lesson. Additional benefits include the opportunity to gather ongoing, authentic assessment data through observation and evaluation of the final product, to teach social skills through actual engagement, to learn from each other, and to scaffold learning for all students.

Drawbacks of using this approach include the amount of time needed to teach and establish the roles and procedures for effective cooperative learning experiences. Extroverted children might take the opportunity to control the situation, whereas other children may sit back and be less engaged in the learning. A final product might not completely represent the ideas of the whole group.

Children need to reflect and analyze how well their groups are working in a developmentally appropriate way. Children should be able to determine how well they listened, if everyone had a turn, and ways that things could work better the next time groups are used. Children should also be able to talk about how they did if they had an assigned role in the group. Children need to discover the consequences of their participation or lack of participation in the cooperative learning group.

Cooperative learning groups can be used with discovery learning, with teacher-directed instruction, or to complete an assessment. Cooperative learning is a safe context for all learners to take risks. Multiple intelligences can be addressed through use of a variety of structures. The practices learned while working in a group can be transferred to lifelong interaction, collaboration, and communication skills for our ever-changing 21st-century world.

COPARENTING

Coparenting refers to the extent to which parents work as a team with respect to raising a child. According to family systems theorists such as

Salvador Minuchin, families consist of interdependent parts, or subsystems, with the family “whole” being greater than the sum of its parts. For a family of three, family members participate in a number of dyadic (two-person) relationships (e.g., parent¹–child relationship, parent²–child relationship, parent¹–parent² relationship). The triadic (three-person) coparenting relationship between both parents and the child represents how both parents and the child function together. As such, coparenting represents the “executive subsystem” of parenting—meaning that it guides the whole family.

Just as coparenting impacts the entire family system, external forces can affect the coparenting relationship, as well. As described by Mark Feinberg in his model of coparenting, the coparenting relationship is built on qualities each parent brings to the relationship as well as the parents’ own family experiences. Thus, the coparenting relationship is both stable and open to change due to internal and external factors such as the developmental level of the child, family socioeconomic status, and culture.

Although coparenting research has often focused on families headed by a mother and father, coparenting is not exclusive to the traditional nuclear family. Coparenting can be applied to any individuals who share responsibilities for raising a child regardless of their biological relationship or living arrangement. For example, coparents could include two mothers or two fathers, a parent and extended family member, stepparents, foster parents, or adoptive parents. Even for single mothers and fathers, there is often another adult who helps care for a child. As such, coparenting is relevant to the lives of most children as most children are raised by more than one person.

Assessing Coparenting

Models of coparenting can be described as having four components: solidarity, undermining, support, and division of labor or shared parenting. The first, solidarity, is based on the level of agreement between parents on child-rearing beliefs and values. Sources of agreement or disagreement can range from discipline to nutrition, and from education to

chores. Coparents with high levels of solidarity grow together as parents, rather than apart.

Undermining is a parent’s hostility toward or criticism of the other parent. Parents who undermine are often displeased with their partner’s parenting techniques and may even ignore their partner. Undermining can be observed through competition between parents for the child’s attention or affection, and sometimes it can manifest through annoyance with a coparent.

Contrary to undermining, support can be instrumental or emotional. Coparents high in support appreciate their partner’s relationship with the child and are actively engaged when their partner takes the lead. In addition, supportive coparenting can also be seen through a genuine connection between parents with regard to parenting. Parents high in support are warm toward each other and reinforce one another’s techniques and directions.

Lastly, the quality of coparenting is reflected in a family’s division of labor. Parent satisfaction with the division of responsibilities that are associated with childrearing is an important indicator of the health of the coparenting relationship. Equality in terms of the amount of work is not as important as satisfaction with each parent’s responsibilities.

When Does Coparenting Begin?

For many families, the birth or adoption of a child marks the moment two people become coparents; however, important decisions are often already being made with regard to the child well before the birth or adoption (e.g., mother’s nutrition, labor and delivery plans, prenatal testing, and even discussions about the care of the infant). Although the transition to parenthood is fraught with many changes in the relationship between coparents, the behaviors of coparents during pregnancy can predict the postnatal coparenting relationship.

For nontraditional coparents, such as foster parents, stepparents, or grandparents, the coparenting relationship is established when the coparents begin sharing responsibilities for the child. Although the beginning of the relationship can be less clear, the development and quality of this relationship is no less important.

Why Is Coparenting Important?

Coparenting is important because, as predicted by family systems theory, it affects the child's social and emotional adjustment. A review of studies by Daniela Teubert and Martin Piquart in 2010 showed that supportive coparenting has been linked to more compliant behavior in children, whereas undermining coparenting has been linked with more frequent and intense externalizing child behavior problems. Moreover, the quality of the coparenting relationship appears to strengthen or weaken effects of other child and family characteristics on child development. The role of the coparenting relationship in the child's social and emotional development is best established during the child's early years; however, the coparenting relationship may play an important role in adolescent development as well.

In addition, research by Sarah Schoppe-Sullivan and her colleagues has shown that for different-sex biological coparents, the strength of the coparenting relationship often predicts father involvement. Because fathers bring unique qualities to parenting, and because children benefit from having fathers who are involved, it is important to recognize high-quality coparenting relationships as supportive of father involvement in childrearing.

Applications of Coparenting to Early Childhood Education

Urie Bronfenbrenner's bioecological systems theory expands family systems theory beyond the family to include additional contexts such as schools, child care, workplaces, neighborhoods, and culture. Broadening the system beyond the family offers an opportunity to see partnerships between other adults who care for children through the lens of coparenting, or rather, cocaring relationships. Sarah Lang's research on cocaring relationships between parents and teachers showed that these relationships have strong implications for child outcomes, just as the coparenting relationship does. Similar to how two parents coparent, parent-teacher relationships depend on communication and are affected

by support and undermining. The application of coparenting to parent-teacher relationships is a new area; however, it is an interesting extension of coparenting theory and it represents research that is gaining momentum.

CREATIVE CURRICULUM, THE

Based on child development and early education research, The Creative Curriculum is a comprehensive set of resources that explain the what, why, and how of teaching young children. There are three versions, each addressing a specific age group or setting: infants, toddlers, and 2-year-olds; preschool children (ages 3 to 5 years); and children who are cared for in family child care homes (birth through school age). The Creative Curriculum is widely used by the majority of Head Start and Early Head Start programs and by other child care, preschool, and prekindergarten programs in every state. It is linked to an online, authentic assessment system with high validity and reliability. This entry describes the philosophy and research that underlie the curriculum, the organization of the curriculum, the way it promotes inclusion, the daily practice resources that support teachers at all levels of experience, the link between assessment and curriculum, and the

research that shows the validity of the assessment system and the effectiveness of the curriculum.

Philosophy

The philosophy of The Creative Curriculum reflects the principles of developmentally appropriate practice defined by the National Association for the Education of Young Children in its 2009 position statement. This means teaching in ways that reflect the way children develop and learn best. Best practices are based on knowledge about child development, the individual characteristics of each child, and cultural and family influences.

The preschool and family child care versions of the curriculum explain the practical implications of five fundamental principles derived from major child development theories and research: Positive interactions and relationships are fundamental to children's learning and development; social-emotional competence is a significant factor in school success; children learn best through constructive, purposeful play; the physical environment has a profound impact on children's behavior and learning; and partnerships with families support children's development and learning. The version for infants, toddlers, and 2-year-olds also helps teachers address the critical aspects of early care and education identified by major theories and research: the importance of meeting children's basic needs, fostering social-emotional development, developing relationships, and supporting cognition and brain development.

Curriculum Format

Since the first edition was published in 1978, The Creative Curriculum has helped teachers understand the importance of creating a dynamic and well-organized environment as the setting for effective teaching and learning. Current editions of all three versions of the curriculum provide resources that offer teachers the knowledge they need to work purposefully with young children and to be responsive and flexible in their interactions. Each set of resources begins with a foundational volume that summarizes the underlying

research and theory, and each follows a consistent framework with the following five components:

1. How children develop and learn
2. The learning environment
3. What children are learning
4. Caring and teaching
5. Partnering with families

In the preschool version, the five components are applied in the 10 classroom interest areas and the outdoors. In the versions for infants, toddlers, and 2-year-olds and for family child care, the components are applied during daily routines and purposeful play experiences. The preschool version also includes knowledge-building volumes that provide comprehensive information and guidance for effectively teaching language and literacy, mathematics, science, social studies, and the arts. The sets for preschool and for infants, toddlers, and 2-year-olds include a volume titled *Objectives for Development & Learning: Birth Through Third Grade*, which explains 38 objectives that identify the skills, knowledge, and behaviors most predictive of school success. These objectives are the focus of all experiences teachers plan as they implement The Creative Curriculum, and they are the basis for the assessment system, GOLD by Teaching Strategies.

Daily Practice Resources

With the publication of the fifth edition of the preschool curriculum in 2010, a new set of daily practice resources was added to offer teachers at all levels of experience more explicit guidance on what to teach and how. Teaching guides provide daily guidance and feature studies, which are engaging, long-term collaborative projects that help children integrate content learning. Intentional Teaching Cards support teachers in planning small group, large group, and individual experiences that focus on language, literacy, mathematics, social-emotional, and physical skills. For the in-between, transitional times of the day, a set of 100

small cards called Mighty Minutes gives teachers easy access to songs, chants, rhymes, games, and other short activities that make every minute of the day a learning opportunity. Book Discussion Cards guide teachers through three read-alouds of storybooks with complex plots, providing suggestions for introducing the story, commenting on the characters, and asking probing questions.

In 2015, daily resources for teachers and providers who care for infants, toddlers, and 2-year-olds were published to provide more support for responsive and intentional experiences. In addition to Mighty Minutes for this age group, the resources include Intentional Teaching Cards that present teaching sequences for offering learning experiences for infants, toddlers, and 2-year-olds. Book Conversation Cards provide guidance for interacting with very young children while reading books in the *Highlights Hello* collection (now part of the curriculum). *Highlights Hello* offers stories, poetry, and other language activities for children from birth through age 2 to enjoy with adults.

An Inclusive Curriculum

Early childhood classrooms today are increasingly diverse, presenting teachers with opportunities to create inclusive classroom communities and challenging them to meet children's widely varying strengths, interests, and needs. The Creative Curriculum provides information and practical strategies for adapting experiences and instruction to ensure that all children, including dual language learners and those with disabilities and developmental delays, can participate fully and benefit from the program.

Researchers such as Linda Espinosa have shown that helping children build a solid foundation in their home language is critical for two reasons: (1) Children are able to retain a sense of cultural identity and remain attached to family traditions, customs, and elders; and (2) children who acquire concepts and skills in their first language are able to transfer that knowledge to acquiring a second language. While supporting families in continuing to promote their children's first language, teachers need to know how children

develop a second language and how to teach concepts and skills to children who do not yet understand the language of instruction.

The Creative Curriculum explains the developmental sequence of second-language acquisition so teachers know what to look for at each stage. Specific strategies for promoting the learning of English are embedded throughout all curricular resources, including social-emotional supports (such as establishing and following regular routines and developing positive and warm relationships with children and families), integrating children's home cultures and family practices into everyday routines and experiences, adaptations to the environment (such as labeling materials and charts in English and the children's other home languages and including literacy materials that reflect children's cultural and linguistic backgrounds), combining nonverbal communication with speech, learning a few words in the children's home languages, and reading books with simple illustrations that provide visual clues about content.

Including children with disabilities in all classroom experiences is not only good practice, it is the law. Teachers should receive specialized support for meeting the specific needs of an individual child. The Creative Curriculum provides information about children with disabilities, offers strategies, and suggests ways to modify the environment when necessary. Strategies include practices such as maintaining a well-organized and clutter-free environment that provides structure and predictability, using picture sequences to illustrate the daily schedule and routines (such as washing hands), preparing children before a transition by explaining what to do, pairing a child with a buddy for an activity, selecting toys that are easy to manipulate (such as puzzle pieces with knobs), and helping children communicate by using gestures and pictures.

Connecting Assessment and Curriculum

To support children's learning, early childhood teachers must be able to adapt instruction to fit each child's development levels. Young children develop

at very different rates and have had very different life experiences. Ongoing, observation-based assessment, structured by a valid and reliable assessment tool, enables teachers to learn about each child's strengths, needs, and interests and to individualize their interactions and instruction.

The Creative Curriculum is linked to an authentic, observation-based assessment system, GOLD. Both the assessment system and curricular resources focus on the same 38 objectives that address all areas of development and learning (social-emotional, physical, cognitive, language, literacy, mathematics, social studies, science and technology, the arts, and English language acquisition). Both resources show the developmental progression for each objective, clearly delineating the predictable sequences of typical child development from birth through third grade. The progressions also identify research-based, widely held expectations for each age group, thereby helping teachers and families identify realistic expectations and illustrating that, even within the range of typical development, children progress at very different rates.

To offer even more support for individualizing instruction, GOLDplus by Teaching Strategies was introduced in early 2015. Used with the GOLD assessment system, GOLDplus enables teachers to use technology to integrate curriculum and assessment. Flexible planning tools are linked directly with assessment data and with electronic versions of curricular resources. For example, when preliminary or final checkpoint data are entered in GOLD, the teaching sequences for Intentional Teaching experiences (electronic versions of the Intentional Teaching Cards included in the curriculum) automatically populate with children's names. These sequences give teachers starting points for individualizing instructional activities to match each child's level with regard to targeted developmental objectives. Additional features include a searchable digital resource library; automatically generated class profile reports; digital "Individual Care Plans" for infants, toddlers, and 2-year-olds; digital family information forms; and a family portal for sharing resources. Preschool programs that use GOLDplus also have the option of accessing

digital resources and learning supports that include research-based media elements from Sesame Street that relate to curricular objectives.

Research

Independent researchers examined the effectiveness of The Creative Curriculum for Preschool during a 2-year study. Although no statistically significant impact was found when the scores of children in control classrooms were compared with the scores of children in classrooms using The Creative Curriculum for 1 year, researchers found statistically significant positive impacts on children's achievement in literacy, mathematics, and spelling when comparing the scores of the control group with those of the treatment group in the second year of The Creative Curriculum implementation. The results of this study suggest that teachers who had more time with The Creative Curriculum were able to increase their effectiveness. Children in classrooms where The Creative Curriculum was not used did not show the same gains in literacy and mathematics.

Several independent research studies have explored the reliability and validity of the GOLD assessment system. The studies involved large, diverse samples of children attending Head Start, private child care, and school-based programs in all areas of the United States. Results indicated that GOLD is a valid and reliable assessment tool.

In another study completed in 2013, researchers followed the educational progress of a nationally representative sample of 11,820 children ages 3 and 4 in programs that used both The Creative Curriculum and GOLD during one academic year. After 1 year, the percentages of 3-year-old children who met or exceeded the GOLD widely held expectation for each area ranged from 71% for mathematics to 91% for the areas of cognition and literacy. For 4-year-old children, the percentages ranged from 60% for mathematics to 83% for physical development.

The widespread use of The Creative Curriculum and GOLD makes it especially important to continually evaluate the effectiveness of both

and to determine whether their implementation promotes positive outcomes for children. Ongoing research, the addition of new curricular resources, and the use of technology that enables teachers easily to link curriculum and assessment as they plan instruction continue to enhance the quality of early childhood programs.

CREATIVITY

Creativity is the process by which original, high-quality, and genuinely significant products are developed. Creativity in young children focuses on the process of developing original ideas—the potential from which products can emerge. Creativity is distinct from intelligence or talent and is critical to complex problem solving. Fostering creative potential in young children provides the developmental pathway to problem solving. Without attention to encouraging fluency and originality in young children, the potential for advanced creative thought and products may be inhibited. For many, defining creativity necessitates three developmental considerations: original (a process seen in young children), high-quality (workable solutions evidenced in older children and adolescence), and genuine significant products (contributions to society as judged by adult societal standards). This entry first explains what distinguishes creativity from other cognitive traits before discussing the developmental course of creativity. It then discusses ways of promoting originality in young children, correlates of creative potential, and how the development of creative potential leads to the generation of ideas and creative problem solving.

Distinguishing Creativity

Creativity is distinct from what is typically considered to be “intelligence” or “talent.” The distinction between creativity and intelligence has been best characterized in the classic work of J. P. Guilford that distinguished between convergent and divergent thinking. Convergent problems generally lead to one “right” answer, whereas divergent problems promote the generation of multiple possible solutions, some of which may be novel and original. The very nature of difficult problems for older children and adults suggests that the first answer that comes to mind is often not the solution, and thus the process of voicing multiple ideas (fluency) is often required to yield unusual ideas (originality) to address the issue at hand. Most

measures of “intelligence” or cognitive abilities lend themselves to convergent modes of thinking in that a specific response is anticipated to be the “correct” answer. “Talent” is evidenced by superior technical skills in a specific area of expertise. Talent, though often associated with the “creative arts” is by no means limited to such activities. Often a talented individual needs highly honed skills to begin using them in an original and novel (i.e., creative) way but talent, itself, does not guarantee that. Neither intelligence nor talent—often considered to be components of being labeled as “gifted”—guarantee that one is creative. Both intelligence and talent may provide a basis that facilitates the expression of creativity but, to be creative, characteristics need to be applied in an original or usual manner.

Developmental Trends

Young children evidence creative potential rather than true creativity if one applies the standard that from the original ideas emerge products that are genuinely significant. Nonetheless, the predilection for fluency and originality is often set in the early years, and the expression of these necessary precursors to creativity can be encouraged in young children. Young children are active scientists as they look to make sense of their world: asking questions, developing theories, exploring ideas. The focus at this stage of development is on process rather than on products. Products tend to emerge later in the developmental sequence and often from the application of an idea to a problem. For quality products, some level of skill is often required as well as originality. An emphasis on products too early in the developmental sequence may squelch the inclination to explore ideas. There exists evidence of a decline in originality on ideational fluency tasks as children move from the early years to middle school. It has been postulated that this decline is the result of a growing emphasis on convergent thinking in the middle grades with testing and a “right answer” orientation being more prevalent, as well as a function of the emerging conformity of middle childhood such that standing apart from one’s peers tends to be less

socially acceptable. This decline in the number of original responses generally lasts through middle school and high school. With young adulthood the percentage of original responses begins to increase to parallel the percentage of original responses generated by young children.

Promoting Originality

Creativity can be developed and encouraged through deliberate action. Ellis Paul Torrance's seminal work focused on the relationship between ideational fluency and originality. This relationship has important implications for early education practice. Originality is a product of exploration and fluency. Fostering original responses in young children often involves enabling sufficient time for the more original responses to emerge or additional prompts such as "what else can you think of." The hierarchy of responses tends to move from the common to the unusual. In adults, brainstorming is linked to fluency and the length of responding tends to drive out more responses. If a child is asked to state all the things he or she can think of that are red, the early responses generated tend to be concrete objects such as "an apple" or "a wagon" or "a crayon." As the number of responses in a given child increase, more unusual responses such as "chicken pox" might emerge. Note that the originality of ideas is also linked to context—"chicken pox" may be highly unusual for most 4-year-olds but also may emerge as a typical response in the middle of an epidemic or local outbreak. Allowing time for exploration is also important as young children interact with material or objects in their environment. As children explore objects, they move from thinking about "what can this object do" to "what can they do with the object." The latter question enables different and more original uses to emerge. Thus, providing the time for exploration coupled with the use of open-ended questions—those that encourage more than a single answer—promote fluency and thus originality.

Correlates of Creative Potential

There is ample evidence that a number of personality, cognitive, and contextual factors influence

the expression of creative potential in young children. Expression of these characteristics is influenced by the significant persons in the child's life such as parents and teachers. Children who exhibit creative potential engage their surroundings. They explore objects and material and do so for extended periods of time. The transition from playing with materials to exploring objects or material requires persistence and time. Children who exhibit more originality tend to be more intrinsically motivated and operate on their own time clock. Internally controlled children are less motivated by external factors and the approval of others for the quality of their output. Limiting the time a child has with a task runs the risk of limiting the potential for increased fluency and originality. The process of creativity at this stage of development derives more from the intrinsic process of discovery rather than reliance on the external evaluation of others or tangible rewards. Curious young children also exhibit more creative potential. That curiosity helps feed exploration and engagement. Curiosity in many ways expands the knowledge base of a child that he or she can bring to looking for original ideas. Nathan Kogan's work on metaphoric reasoning helps demonstrate that those individuals who could make more distant and less typical connections between issues and ideas demonstrated better creative problem solving. These remote associations promote originality. Fantasy and imagination do much the same. The child who plays with mental imagery is less bound to the traditional ways of looking at things and can more readily envision the possible. These characteristics are tied to the ability of children to move outside of the generally accepted norms. Nonconformity is often seen as a critical component of creative potential. The nonconformist is less concerned about the evaluations of others and thus is more likely to stretch the bounds of the possible. On the other hand, nonconformity for the sake of being different is not the same as being comfortable with "thinking outside the box" or "drawing outside the lines." Children who take such risks must be provided with an environment that accepts risk-taking. Proposing original ideas always involves risk, and

that is where the focus on internally driven satisfaction rather than externally derived rewards plays a critical role. In addition, children with creative potential show a propensity for a willingness to try the difficult—to try something new without a guarantee of success. Original problem solving by its very definition means moving outside of the well-established patterns of performance. Acceptance of a level of uncertainty speaks to the characteristic of ambiguity tolerance. As creativity emerges, the pathway is often not well laid out and the route to the solution is not evident. A tolerance for ambiguity is required in dealing with what are labeled heuristic tasks in which the route to the solution is not immediately evident. If others in the lives of young children lack such tolerance, the creative potential of the child will often be squelched because that child will not find viable opportunities for the self-expression that underlies creative thought.

Beyond Creative Potential

Creativity, within the early childhood education context, is more appropriately identified as creative potential with the emphasis on the process of facilitating ideational fluency (the generation of ideas) and originality (the generation of atypical and nonnormative ideas). A more mature definition of creativity includes original ideas that are of high quality and contribute to addressing a significant societal critical issue or problem. For younger children, the emphasis is on process rather than on product as a precursor to what will be. A focus on product too early in the development of creativity (i.e., incorporating a process that inevitably entails an external evaluation) runs the risk of limiting the child's confidence in practicing ideational fluency and originality. The development of creative potential in early childhood leads to more effective creative problem solving as the child gets older.

Creativity is not limited to the "creative arts" but rather is evidenced throughout society. Effective problem solving for the complex issues that adults so often grapple with relies on ideational fluency. The generation of a wealth of ideas increases the chances that an issue can be viewed from multiple

perspectives, enhancing the odds of successful resolution. One of the advantages of a diverse group in a team problem-solving session is that those individuals with different experiences, cultural backgrounds, traditions, and societal views can contribute original ideas to the process. Creativity enables movement from the normative to the possible—from what is expected to what can be.

CRIME, EARLY CHILDHOOD EDUCATION AND

Numerous studies of high-quality early childhood education (ECE) programs have found they led to a reduction in crime or led to other outcomes linked to a decrease in criminal behavior. These programs can lead to less abuse and neglect, fewer

behavior problems, better performance in school, fewer high school dropouts, and, ultimately, fewer crimes committed and a reduction in the number of prisoners. This entry summarizes the research linking ECE and crime reduction.

ECE Contributions to Crime Reduction

There is a well-documented relationship between education and crime. According to a U.S. Justice Department report from 2003, seven out of ten state prisoners do not have a high school diploma. Economists who studied the relationship over time between changes in graduation rates and crime concluded that a 10 percentage point increase in graduation rates reduces murder and assault rates by about 20%. One of the best ways to keep young people from dropping out of school and becoming criminals is to make sure they have a foundation for success in their earliest years. Research has demonstrated that high-quality ECE can result in more successful outcomes, culminating in a reduction in crime and incarceration.

Less Abuse and Neglect

The Chicago Child-Parent Centers (CPC) is an ECE program that has served more than 100,000 children and followed a sample of them up to age 28. This program also coaches parents to help them understand their children's health needs, create safer home environments, and develop parenting skills. CPC cut child abuse and neglect (reports to child protective services) in half for the children served, compared to similar children from families not being helped.

Fewer Behavior Problems

An independent evaluation of Pennsylvania's Pre-K Counts public-private partnership found that the program cut the portion of 3-year-old children at risk for problematic social and self-control behavior from 22% to 4%. (At-risk status was defined as scoring above the cutoff on the behavior scale of the Basic School Skills Inventory-3.)

School Readiness

Boston's universal prekindergarten program improved mathematics, literacy, and language skills among participating children equivalent to 7 months of additional learning, compared to children who did not attend. Other states' ECE programs have also reported important improvements in school readiness.

Better School Outcomes

Researchers who studied New Jersey's preschool program, which serves disadvantaged school districts statewide, found that by fourth and fifth grades, children who attended the program were 31% less likely to be placed in special education and were held back a grade 40% less often than a control group. Participating children were also three fourths of a year ahead of the control group in math and two thirds of a year ahead in literacy.

Fewer Dropouts

Researchers have found that participants in the Chicago CPC pre-K program were 29% more likely to graduate from high school by age 20 than similar children not enrolled in the program. Other researchers found participants in Michigan's Great Start Readiness program were 35% more likely to graduate from high school and those who attended the Perry Preschool program were 44% more likely to graduate from high school.

Less Crime

Children *not* served by the Chicago CPC program were 70% more likely than participants to be arrested for a violent crime by age 18. By age 27, children *not* served by the Perry Preschool program were 5 times more likely than participants to be chronic offenders with five or more arrests.

Fewer Prisoners

By age 24, those who participated in the Chicago CPC as children were 20% less likely than nonparticipants to have served time in a jail or prison. By age 40, the children served by the

Perry Preschool program were 46% less likely than nonparticipants to have been sentenced to prison or jail.

In sum, childhood abuse and neglect, insufficient preparation for school, unaddressed behavior problems, poor academic performance, and dropping out of high school all can lead to criminal behavior. School readiness, the ability to get along with others, academic achievement, and graduating from high school all help individuals lead more successful lives. One reason certain states have increased their investments in ECE in recent years is because of the findings indicating that it is a way to reduce crime.

Economic Benefits of ECE and Crime Reduction

To obtain lasting results, including reductions in crime, ECE programs must be high quality. Programs need to have qualified teachers and program results must be rigorously measured in order for even stronger results to emerge. Research has shown that the investment in ECE brings a net benefit to society. A cost-benefit analysis by the Washington State Institute for Public Policy of more than 20 different studies of state and district ECE programs showed a return of, on average, a “profit” (economic benefits minus program costs) to society of over \$26,000 for every child served. These economic benefits accrue largely as a result of reductions in the cost of future crime and increases in participants’ future wages as a result of graduating from high school.

CRITICAL THEORY

Critical theory developed from various ideas emerging from the Frankfurt School of Critical Social Theory in the late 1930s. It is part of a wider intellectual tradition that critically engages with Marxist concepts and other philosophical traditions. It is grounded in a vision of a democratic society in which people live together in ways that are generous, compassionate, and socially just. It is considered a sociopolitical theory because it is concerned with issues of power and oppression. In particular, critical theory is interested in how economies, race, social class, sexuality and gender, abilities, age, education, religion, and other institutions interact to

construct a social system. Critical theory is relevant to the field of early childhood education because it assumes that education is a social and political activity that affects the life chances (both positively and negatively) of children involved in it. This entry explains critical theory and its purpose in education and then gives examples of how various elements of critical theory come into play in the early childhood classroom.

Critical theory offers teachers a range of conceptual tools to consider how power operates in education in relation to knowledge and authority. Most importantly, educators use these tools to question taken-for-granted assumptions (or ideology) the field holds true about teaching, learning, childhood, and curriculum. Critical theories view all beliefs, values, and realities within their social and political contexts. By asking hard questions such as “Who gains and who loses in this classroom from seeing things in particular ways?” or “Who would gain and who would lose if an alternative view were accepted?” critical theory sets out to locate and understand inequalities and oppressions. By uncovering whose values and knowledge perpetuate particular truths about early childhood education, a critical perspective believes that it then becomes possible to create more inclusive and socially just forms of curriculum.

An aim of critical theory is to critique *and* change society. This is different from other social theories because they aim to understand and explain society, not transform it. In this sense critical theory is considered radical, emancipatory, and a theory for change.

In the field of education, Paulo Freire (1921–1997) is considered a central figure in the development of critical education and is often associated with critical theory. He was a Brazilian educator who taught peasant farmers to read and to understand how the power structures of the dominant society worked to oppress them. He was devoted to education that would improve the lives of marginalized groups of people.

Freire used the term *banking education* to describe and critique traditional educational systems that rely on a transmission model of teaching and learning.

This kind of model assumes that students are empty vessels into which teachers deposit knowledge. A banking model of education lacks critical thinking and fails to recognize the knowledge and strengths that students bring to the classroom. As a result, this kind of education reinforces the status quo and reproduces oppression. Freire and critical theory advocate for a kind of education that positions teachers as intellectuals and change makers.

To do this transformational work, critical early childhood educators must first become conscious that their own thinking and the traditional early childhood curriculum that they have enacted are limited and oppressive. By drawing from Freire’s work, teachers can place themselves and their values and beliefs within social, cultural, historical, and philosophical frameworks. This allows teachers to gain a sense of how different groups of people (e.g., girls, boys, single mothers, Indigenous children and their families, low socioeconomic status [SES] families, second-language learners, children with additional needs) are situated within the wider world in general and the early childhood classroom in particular. This image of a teacher is not that of a technician who simply follows the instructions of others. Instead, a critical educator is an intellectual, who is aware of social issues and how they are working in complex ways to marginalize particular groups of people while benefiting others. However, a critical educator does not stop at becoming aware of these issues. Instead, a critical educator names these inequities, critically reflects on them, and then acts.

Critical theory teaches us that education is always political and that teachers are part of this process. Education can be transformational, but it can never be an individual process. Therefore, critical educators must build alliances with others (colleagues, families, students) to reconstruct new knowledge together.

How Critical Theory Comes to Life in the Early Childhood Classroom

Early childhood teachers use concepts that come from critical theory to think about, negotiate, and

transform the relationships between teaching, learning, and power. In particular, critical theory provides teachers with conceptual tools to consider how power operates in the early childhood classroom in relation to knowledge and authority.

Some examples of these conceptual tools and how critical theory comes to life in the early childhood classroom include the following.

Praxis

Praxis is the reciprocal relationship between theory and practice. The theory building and critical reflecting that teachers do with others (children, colleagues, families) constantly inform how they think and what they do. These practices and actions generate more theory building and critical reflection, as seen in this scene, based on a real classroom:

An early childhood teacher enters her classroom with the belief that all children should be able to choose where they want to play during free-choice time. She notices that the boys always go to the Lego center and wonders why none of the girls ever go to play there. After talking with the girls, she discovers that the boys always pick this center to play at first, they stay there during the whole center time, and when a girl does get a chance to play there it is “too noisy and loud.” The teacher decides to change the classroom rules. Instead of giving children free choice of where they will play, she decides that twice a week only girls will be allowed to play at the Lego center. The teacher begins to wonder how other classroom rules and practices might be benefiting some groups of children while excluding others.

Problem-Posing

Problem-posing is central to critical teaching. Critical educators use a range of teaching methods and strategies for asking questions that reflect real issues in children’s lives. It can make teachers uncomfortable because it attempts to ask hard questions and offer real solutions. These solutions then generate new practices:

When the teacher realized that free-choice time was not so “free” for some groups of children (the girls) she decided to change the classroom rule to provide girls the opportunity to play in the Lego center. After trying this out for a week, she held a class meeting to discuss the problem, why she thought it was a problem, and to find out more about what the girls and boys in the class thought about the problem and her solution. She wanted to create a space in the curriculum for the children to come up with solutions and to make links with other aspects of classroom life that might seem unfair. After a productive discussion about the problem of only boys going to the Lego center, the boys being noisy and unfair to the girls who went to the center, and her failure to enforce the classroom rules for the boys, the class came up with some interesting solutions. By bringing the Lego problem to the class, the teacher uncovered more issues about fairness in relation to Legos. She found out that the girls did not think it was fair that Lego made Lego pieces “mostly for boys.” A group of the girls decided to write a letter to Lego asking why the company makes fewer Lego girl figurines than boy figurines. The teacher highlighted the class meeting in her weekly newsletter and encouraged families to ask their child more about it and to talk about issues related to fairness.

Hegemony

Hegemony is a term associated with the Italian Marxist political economist Antonio Gramsci (1891–1937). Hegemony is the domination of one group over another with the partial consent of the dominated group. Hegemony exists on both macro and micro levels. Gramsci believed that the process of hegemony is pervasive and infiltrates all aspects of life. It is lived out in the early childhood classroom.

After observing the play for 4 weeks at the Lego center, the teacher noticed that the boys were usually the group of children who played there. On the few occasions when the girls did go to this center, they would only stay for a few minutes.

The teacher realized that the girls did not engage with complex building or problem solving because they never had a chance. The boys would often make fun of the girls' work, take pieces of Lego away from the girls, or hide Lego pieces from the girls. When the boys got excited with their own building and started to get loud, the girls simply got up and left. The teacher then started to wonder what part she might play in the boys' behavior and ultimately in the girls' lack of play opportunities with Legos. To her dismay, she realized that she never asked the boys to "settle down" because they might be disturbing others. It seems as though she accepted this kind of "boy" behavior as "normal" and never questioned or stopped it.

Hidden Curriculum

The *hidden curriculum* is a term used to describe the unarticulated and unintentional messages that children receive while taking part in everyday classroom activities that make up the early childhood curriculum. Although it is happening everywhere and all of the time, the hidden curriculum is covert and difficult to see. Because it is hidden, the curriculum conveys attitudes and values implicitly to children. Hegemony supports the hidden curriculum, and it is often exposed through problem-posing.

When children are allowed to "freely" choose a center to play at during free play time, they are learning that particular groups of children get more choices than others. For instance, all of the children are learning that boys get to be louder in the classroom than the girls, that boys get more chances to play with Legos than girls, and that girls' Lego play is not as important as the boys' Lego play. In short, they are learning that the classroom is fairer for some groups of children and not others.

CULTURAL AND LINGUISTIC RESPONSIVENESS

Migration between and within countries has increased dramatically in the past few decades around the world. More people leave their communities in search of a better life for them and their children; they are escaping poverty, leaving political instability and violence, or being recruited for their skills and talents. There also are large numbers of indigenous communities in many countries whose cultures and languages are different from the mainstream or dominant culture and language. They are struggling to maintain or revitalize their languages and cultures of origin. As a consequence, millions of children are growing up in communities characterized by increased cultural, ethnic, and linguistic diversity. This entry discusses early childhood care and education in multilingual and multicultural societies, bilingualism, and issues of quality and equity in early education.

Some authors, such as Jan Blommaert and Steven Vertovec, are using the term *super-diversity* to refer to the complexities of diversity in the globalized societies of the 21st century. They propose that diversity should not be defined only in terms of ethnicity, as is usually the case among social

scientists, policy makers, and practitioners, but that the term should involve characteristics of the migrant populations and their experiences to fully understand the diversity within these diverse population groups, such as their migration histories, employment experiences, and access to services, among others.

Children in these migration-driven diverse communities usually grow up in environments in which their families speak a language other than the one spoken by the host country or community, usually referred to as a “minority language.” For these children and their families, schooling, health care, and other social services, as well as employment, usually occur in the mainstream or dominant language, which often becomes a barrier for families to access those services. For their young children, growing up in two worlds has the potential to be a negative experience, associated with school failure. National statistics and evaluation studies conducted in the United States (e.g., by Kathryn Lindholm-Leary and Graciela Borsato), Latin America (e.g., by Arlette Beltrán and Janice Seinfeld), and Europe (e.g., by Asako Ohinata and Jan C. van Ours) indicate that children of immigrants and migrants from minority-language backgrounds have lower school achievement than those who speak the dominant language as their only or primary language. One factor that can help explain this outcome is the strong association between poverty and minority-language status.

Another factor can be the inadequacy of an educational system designed with middle-class, monolingual children in mind and thus not responding to the characteristics of culturally diverse, emergent bilingual children. The unique experiences of bilingual children, who are growing up in socially complex community and family contexts, will determine particular pathways in their development and learning processes. Therefore, early care and education offered to them should be tailored to address their specific characteristics and needs. Both the sociocultural context and children’s bilingualism should be taken into consideration when developing policies and implementing practices for bilingual/bicultural children.

Bilingualism and Children’s Development

Research has confirmed that bilingualism affects children’s cognitive, language, literacy, and socioemotional development in particular ways. Furthermore, in recent years neuroscience research, conducted by Barbara Conboy and others, has shown that bilingualism generates changes in both brain function and structure. Regarding language development, for example, a review of studies with successive and sequential bilingual children by Carol Scheffner Hammer and colleagues has indicated that there is considerable variation in their rate and patterns of development and that this variation is often associated with the age of onset of second-language acquisition and the amount and quality of exposure to each language. Similarly, the cognitive advantages of bilingualism have been well established in the research literature, specifically in the areas of executive function, and the advantages are larger in children with advanced skills in their two languages, according to a review conducted by Raluca Barac and colleagues. Wen-Jui Han reported differences in socioemotional development have been found between bilingual children and their monolingual English-speaking peers, with bilinguals obtaining higher scores on measures of self-control, interpersonal skills, and fewer internalizing and externalizing behaviors.

There is a tendency to treat bilingual children as two monolinguals in one, and, in spite of the research evidence, educational policies and instruction tend to focus only on one of these children’s languages, the dominant language. When policies and practices ignore children’s bilingualism, “they perpetuate inequities in the education of these children. That is, they discount the home languages and cultural understandings of these children and assume their educational needs are the same as a monolingual child” (Garcia, Kleifgen, & Falchi, 2008, p. 6).

Defining Quality of Early Education Practices

High-quality early education has contributed to reduce the school readiness gap for children from

racial/ethnic minority groups who live in poverty (Bowman, Donovan, & Burns, 2001). In fact, reviews of the research literature have found that what is considered high-quality education for monolingual children is beneficial for bilinguals; however, that alone is not enough for bilingual children to perform at the same levels as monolinguals, states Claude Goldenberg. This indicates that there is a need to identify additional instructional strategies or modify current practices to make them appropriate and effective for bilingual/bicultural children.

The notion that without equity, the goal of offering children high-quality early education experiences cannot be reached should be at the forefront of the discussion on quality in early care and education. Equity is not about treating all children in the same way or exposing them to the same activities or using the same instructional practices. It is about acknowledging children's characteristics, by designing educational experiences that build on children's prior knowledge and ways of knowing, and valuing what they can contribute from their own perspectives. Therefore, the definition of quality cannot be static; to the contrary, it should be flexible and dynamic. How indicators of quality are operationalized and those that are relevant indicators of quality may change depending on the attributes of the communities where programs are being implemented.

In the past 15 years, the emphasis on accountability in early education has grown in the United States, as it has in other countries. Federally funded programs such as Head Start developed the Head Start Child Development and Early Learning framework, and most states now have quality rating and improvement systems (QRISs) for early care and education. The Head Start Child Development and Early Learning framework includes a section dedicated to dual language learners (i.e., emergent bilinguals), and, as documented by the BUILD Initiative, there is great variability in the approaches used by states' QRISs to assess whether the care and education needs of children from diverse ethnic, cultural, and linguistic families are being met. The main challenge faced by states is the absence of a definition of

what constitutes high-quality early education practices for bilingual/bicultural children.

One proposal is that the provision of an early education that is culturally relevant and linguistically appropriate for emergent bilingual children requires a holistic, intentional, and systematic approach and should include the following elements. First, program leadership and decision-making processes should support development of children's two languages, such as hiring bilingual/bicultural teachers and program staff and implementing bilingual intercultural education programs. Second, prepare professionals and offer ongoing professional development for teachers to acquire pedagogical and content knowledge and skills for working effectively with bilingual and culturally diverse children. Besides content knowledge, teachers should have beliefs about bilingualism and interculturalism that promote development and learning, as well as dispositions that are strengths-oriented. Third, develop and implement a curriculum that goes beyond respect and celebration of the "other's" cultures and reflects children's worldviews, beliefs, values, and experiences. The social organization of learning in the classroom should honor children's participation in intercultural experiences that are integral to the shared practices of their community, using children's cultures and languages as resources for learning. Fourth, establish partnerships with families and communities to facilitate learning about children, families, and their experiences and ways to support them at home and in school. Child-rearing beliefs and practices vary across cultures and will influence the ways that children are socialized in their families. Learning about those beliefs and practices will help in the process of making the curriculum culturally relevant. Also, gathering information about parents' expectations and goals for their children's bilingual development will be essential to inform classroom practices.

New Challenges

Increasing diversity within diverse populations presents the field of early education with new challenges. For instance, while efforts are emerging to

provide high-quality early education to bilingual/bicultural children by promoting models of care and education that support the development and maintenance of children's two languages, a new challenge is the multilingual and multicultural composition of communities and, hence, of classrooms. It is becoming more common to find classrooms where several different home languages are spoken. How could the development of bilingual children's two languages be supported in a multilingual environment? The research literature is very limited on this topic. Recommendations are made from experiences in the field that have not been evaluated yet, or they come from research conducted with older children. Some of those include exposing children to different languages and cultures through music experiences, labeling the classroom with different home languages spoken (using different colors for each language or using different languages on alternate days or weeks), and making books available to the children in different languages and reflecting diverse cultures. In addition to exposing children to home languages, sheltered instruction strategies could be used to assist with teaching new vocabulary and comprehension of content for all children whose first language is not the language of schooling. They include the use of visual aids, such as props, pictures, and graphic organizers, as well as gestures, body movement, and hands-on activities to demonstrate concepts, as Goldenberg and colleagues suggest. Multilingual and multicultural classrooms offer a great opportunity for children to learn about languages and cultures that differ from their own and to develop a multicultural identity that will make them the global citizens of the future. More research is needed that will help identify teaching principles and strategies that will ensure equitable access to content and supports for learning for all children in the new "super-diverse" early education programs.

CULTURAL COMPETENCE

Cultural competence refers to awareness, knowledge, and skills that result in respect for and valuing of culturally and linguistically diverse groups of people and the ability to acknowledge multiple perspectives. It involves a critical analysis and understanding of how different value systems and belief systems relate to one another and coexist within various social contexts. This includes an understanding of how power dynamics between social identities, defined by value systems and belief systems, shape social relations between groups (intergroup), within groups (intragroup), and at the individual (personal) levels.

Overview

Cultural competence in early childhood education is the engagement and valuing of all knowledges. This is in contrast to a preparation for a future of schooling that narrows the definition of what counts as knowledge and often promotes a dominant culture as being of most worth. The concept of cultural competence is to acknowledge the existence of different cultures at the systemic (schooling) and individual (educator) levels and to work toward an understanding and valuing of difference through critical self-reflection. This can be difficult work for educators of young children because dominant beliefs deem a future of narrowly defined possibilities as best for young children. Cultural competence during early childhood strives to foster perspectives

that open up possibilities. The epistemological and ontological implications of considering multiple possible ways of being are done through critical self-reflection by educators working alongside young children as co-learners.

The work of educators seeking to develop cultural competence involves a process of moving toward more equitable social relations. Central to the development of cultural competence in early childhood education is a broad philosophical consideration and understanding of systemic forces and how systemic and individual-level forces interact. This is important for the development of social justice dispositions in young children and the imagining of equitable social relations.

Research

The conceptualization of cultural competence is based in many academic disciplines, including education, language, psychology, nursing, and sociology. In the context of early childhood education, research includes exploration of teacher education, educator attitudes and practices, and early childhood development. Within the discipline of education, research around cultural competence over the past 4 decades has not settled on a single definition, and the main principles of cultural competence are debated. Researchers' own historical contexts and sociopolitical positioning shape and impact their understandings of cultural competence. However, a common base assumption in research is that cultural competence encompasses three key components: awareness, knowledge, and skills.

The three fundamental components are based on ideals of equitable social relations. First, culturally competent educators strive to practice critical self-reflection (awareness) focused on rethinking normalized ideologies and critiquing dominant and supremacist/imperial systems of thinking and being. Second, culturally competent educators develop a broad and deep understanding (knowledge) of the cultures that young children bring with them and appreciate these cultural differences as assets rather than deficits. Third, culturally competent educators engage in transformation alongside young children, caretakers, and community

members and practice pedagogical methods (skills) that embody the awareness and knowledge of cultural competence. This also requires culturally competent educators to advocate for the transformation of oppressive social relations and actively work for socially just transformation.

Theory

The definition of cultural competence must begin with understanding what is meant by both *cultural* and *competent*. *Cultural*, in this case, means diverse and nonhierarchical epistemologies and ontologies, both inside and outside the bounds of Western European Enlightenment rationality and modernity. *Competence* means awareness at various levels and through diverse modes of understanding, ultimately recognizing the prism-like fractioning of understandings that are possible in the construction of the social world and how social relations are engaged. Cultural competence asserts that understanding issues of diversity should go beyond mere knowledge of cultural differences. Moving beyond knowledge involves work that seeks to critique and transcend delineated ways of knowing and being, in an attempt to transform or transcend Western conceptualizations of epistemology and ontology. Within early childhood education the practice of cultural competence by educators and young children brings together popular and social understandings of historical social difference based on identity with academic understandings and, perhaps most significantly, with philosophical considerations of how difference operates in the construction of reality.

Foundational scholars in education that have contributed to the conceptualization of cultural competence include James Banks, Cherry A. McGee Banks, Geneva Gay, Christine Sleeter, Carl Grant, and Sonia Nieto.

Framework and Strategies

In educative practice, cultural competence is the holistic incorporation of social justice understandings of sexuality, race, gender, (dis)ability, socioeconomic

status, religion, language, family structure, nationality, ethnicity, ideology, species, and other social identities. Cultural competence is necessary not only in settings traditionally thought of as diverse, such as urban classrooms, but also in all formal and informal education settings. There are many forms of diversity that are often overlooked, such as communication styles and patterns, linguistic preferences (e.g., nonstandard English), relationships to time, views of (dis)ability, and conceptions of family roles, for example.

Accreditation bodies of teacher education programs are increasingly developing standards that require future early childhood educators to work in diverse settings and be provided opportunities to develop multicultural dispositions. However, there is little consensus on how to encourage the development of cultural competence in teacher education programs. One challenge in the work of developing cultural competence in early childhood education is the lack of educators who are themselves culturally and linguistically diverse. Research shows that the largely monocultural (female, White, Christian) population of early childhood educators and caregivers often embodies White, “middle-class” normative practices. One of the first steps in moving toward being a culturally competent educator is the awareness, beyond a superficial comprehension, that one’s own way of being in the world is socially constructed.

Early childhood educators wishing to cultivate the awareness and knowledge necessary for developing cultural competence can do so in the following ways:

- Critically reflect on the cultural influences on one’s own beliefs, thoughts, and behaviors.
 - Seek out cross-cultural experiences, such as discomfiting experiences, that decenter one’s own worldview as the “norm” and allow oneself to confront previously unchallenged beliefs.
 - Develop an ability to understand and value difference.
 - Acknowledge and understand that teaching is a political act, that there is no neutrality in education, and that no educator is unbiased.
 - Recognize that formal education systems operate within systems of institutionalized oppression (e.g., racism, sexism, and classism).
 - Develop and practice empathy through critical self-reflection and the cultivation of a critical consciousness.
- Within the field of multicultural teacher education, as it relates to cultural competence, there have been many calls for the enhancement of pedagogical skills for working with increasingly diverse student populations. It has been argued that culturally competent educators, equipped with strong social justice dispositions, are especially important in early childhood education because the attitudes and beliefs of young children are highly malleable.
- The pedagogical skills and strategies that support the practice of cultural competence include the following:
- Create supportive learning environments for all young children from all backgrounds.
 - Celebrate and respect diversity and difference in non-tokenistic ways.
 - Interact respectfully and appropriately with young children, families, and community members of all cultural backgrounds.
 - Enact culturally relevant pedagogy and culturally responsive teaching.
 - Embed oneself in the communities of students and work alongside community members and organizations as an advocate and possibly activist through the development of a critical consciousness.
 - Consciously reject a deficit mentality; hold the same expectations for all students.
 - Practice the ability to understand others’ worldviews.
 - Foster a way of being that embodies respect for diversity.
- The skills and practices of cultural competence require early childhood educators to develop a critical, social justice stance so that the inclusion of topics of diversity is not done in a tokenistic way as an add-on to existing curricula. Respect for diversity is infused into every aspect of the classroom

culture and curriculum, including in relation to classroom management and the physical space of a classroom. This is in contrast to a superficial celebration of diversity, such as decorating a classroom for Cinco de Mayo or reading books with Black characters only during Black History Month.

Young children internalize social understandings of U.S. society based on gender, race, and class. To not engage with young children around the concepts of gender and race, often based on a belief that young children are not ready for such engagement, is to maintain a willful denial of how the social world in which young children exist is constructed. Through transformative self-work, educators seeking to develop cultural competence should challenge the willful denial of social relations built by a colonial world system that maintains oppression and systems of inferiority/superiority. Because the social identities of each child inform his or her positionality in the social world, a bare analysis of the inequities based on hierarchical social identities can only benefit young people in understanding what is unjust and to begin to imagine equitable alternatives.

Multicultural teacher education asserts that meaningful curricula combined with relevant pedagogical approaches are grounded in broad and deep sociological understandings of the various cultures that individuals carry with them into a formal educational setting. An example of a culturally competent approach on the part of educators is the development of relationships with the caretakers of young children and with members of the communities in which young children are situated. The understanding of how social relations operate between the educator self and socially different others can provide culturally relevant insight on the part of the educator and aid the development of cultural competence.

Social relations based on historical oppression (oppressed–oppressor relationality) are of curricular importance in understanding how power dynamics operate based on social identities in contemporary societies. The example of slavery in the United States and its influence on contemporary racial identities, as created by the U.S.

Declaration of Independence, holds promise for exploring White racial identity and in supporting young children’s understanding of how racial identity intersects with other social identities based on dominant ideologies. An examination of slavery in the United States provides opportunities for young children to develop philosophies of social equity. In turn, educators learn from young children. The student–educator relationship is dialectical in nature when educators have developed cultural competence.

The imagining of an equitable society is difficult work if early childhood educators have not previously rethought dominant social norms. The example of slavery in the United States highlights the exclusionary discourse within the dominant narrative around the creation of the United States as a nation-state. The contradiction between fighting for independence in the U.S. revolutionary war and the reality of the enslavement of certain people is rarely part of the dominant historical narrative. This is a simple example from the U.S. context, and culturally competent educators must constantly critically self-reflect and move beyond a delineated conceptualization of knowledge. This can be difficult work for early childhood educators as they rethink what is considered normal within their conceptions of self, nationality, and race. Such an approach necessitates a commitment to the struggle of confronting difference when an educator’s values and beliefs are challenged by young children’s learning processes and the cultures they bring into the formal educational setting. The education of young children is not simply preparation for later learning. Rather, learning from multiple forms of knowledge can be engaged as an existential endeavor for the purpose of social justice and social equity.

anthropologists in their analyses of the behavioral patterns and normative customs of groups (Garcia, 2003).

The culture concept, with its technical anthropological meaning, was first defined by Edward Tylor in 1871 as “that complex whole which includes knowledge, belief, art, law, morals, custom, and other capabilities and habits acquired by man as a member of society” (Kroeber & Kluckhohn, 1963, p. 81). Over time, various perspectives and definitions have been put forward. These modifications and adaptations have included Tylor's elements but also have come to acknowledge constructs that are more useful in understanding the development, change, and measurement of culture. Most adaptations agree that culture is learned, but recent thinking has also begun to consider biological transmission factors of culture (Garcia & Garcia, 2012).

Group-Oriented Culture Concept

Most concepts of culture begin with the notion that individuals who share similar social elements form a culture. This formulation is useful for comparisons between societies or subgroups within societies. Its basic assumption, however, is that of uniformity in the cultural elements. The individuals within the cultural group are assumed to have all the same social elements.

Yet, it is important to acknowledge that members of a culture display differences in their behaviors and ways of thinking and valuing—members are very diverse in their sharing of even the most common elements of a culture. Therefore, cultures are characterized by intracultural heterogeneity. Unfortunately, such discussions remain most often at the level of group description regarding cultural systems. Individual differences are understood as background.

Adopting a group-level definition of culture, even though it acknowledges diversity within the group, generates a problem for understanding the important meaning of heterogeneity within the group. A teacher confronting a student from a different cultural group may ascertain that the key elements of importance for that student are the

CULTURAL DIVERSITY

When we speak of “the culture” to which an individual belongs, our reference is generally to the system of understandings (values, prescriptions, proscriptions, beliefs, and other constructs) characteristic of that individual's society or to some subgroup within his society—that is, ethnic minorities, social classes, countercultures, generations, sexes, and occupational groups. This is the traditional notion of culture employed by functionalist

cultural elements of the group. Therefore, a group-oriented notion of culture may serve to detract the teacher's attention from individual attributes of the student as it relates to the instructional process. Most unfortunate is the stereotyping that may occur by the teacher, providing a more generic understanding of the student's culture and missing important individual attributes of the student. The overall "connection" between the teacher and the student may be at risk, leading to limited and/or inappropriate instructional interaction.

A situation common in the United States places a teacher in the role of instructing one or more students who may speak a language other than that of the teacher and who have immigrated recently from outside the country. Utilizing a group-oriented cultural perspective, the teacher may search for an understanding of these students by comparing the students' behavior to the cultural elements that characterize members of the students' cultural groups. By doing so, the teacher, as an amateur cultural anthropologist, misses the meaning of the important individual attributes of the students as they relate to the cultural practices of the ethnic group and the instruction to be provided.

The Individual-Oriented Culture Concept

Anthropological, sociological, and psychological approaches to culture and learning contain an individual-oriented conception of culture developed and utilized significantly in applications to education. These conceptualizations attempt to address the individual in the context of a participant in an organic view of culture. An early expression of the individual-oriented concept of culture is seen in the work of J. O. Dorsey. Edward Sapir (quoted in Garcia & Garcia, 2012, p. 86) wrote the following of Dorsey's orientation:

Living as he did in close touch with the Omaha Indians, [Dorsey] knew that he was dealing, not with a society nor with a specimen of primitive man . . . but with a finite, though indefinite, number of human beings who gave themselves the privilege of differing from each other not only in

matters generally considered as "one's own business" but even on questions which clearly transcended the private individual's concerns.

An individual-oriented conceptualization begins with the foundational principle that an individual's culture is best thought of as the individual's participation in a pool of constructs (rules, beliefs, values) by which she or he orders the objects and events of her or his life. The specific participation of any individual of the culture in this pool is seen as variable. An individual is also acting on the culture as she or he manipulates, recombines, and otherwise transforms inherited constructs. This variable participation is a major source of culture change and cultural diversity. An implication of this approach to defining and working with cultural diversity can be seen as a rejection of the traditional assumption and implies that each individual's portion of the culture differs in some ways from those of the other members of a society with many identifiable and traditionally defined cultures.

For instance, in efforts related to understanding "Hispanic" culture, we begin with the notion that individuals identified as "Hispanic" are quite diverse in various domains of the traditionally defined culture. Therefore, each individual is considered unique in attributes related to the culture. There is still recognition that the individual shares some traits with the "Hispanic" cultural group. But the focus is on the individual's traits. Cultural integration is a crucial variable in the analysis of Hispanics, and its process contributes significantly to the existence of the heterogeneity of "Hispanic" cultures. Writing of Chicano culture, Frank Bean and Marta Tienda (1987) note, for example, that among Chicanos "many have ancestors who came to North America several centuries ago, but others are themselves recent immigrants. Hence, a simple cultural characterization of [this] ethnic group should be avoided" (p. vii). It is just not a matter of replacing Mexican traits with new American traits. Instead, traits may merge and new traits may evolve as a function of the interaction of the individual with new and diverse individuals and institutions. This makes our understanding of this

population much more complex but much more informative. This more informative approach does not negate the significance of customs—behavioral routines passed on from one generation to another. Referring to the “layered” nature of culture, medical anthropologist Benjamin Paul (1969) observed,

What we call customs rest on top and are most apparent. Deepest and least apparent are the cultural values that give meaning and direction to life. Values influence people’s perceptions of needs and their choice between perceived alternative courses of action. (p. 33)

What needs to be emphasized in understanding cultural diversity is the significance of broader characteristics of the notion of culture (we share a similar pool of traits that identifies us as a member of a culture) and how the individual interacts with that pool and other cultural pools. Educationally, we are asked to consider this intersecting conceptualization simultaneously. In doing so, we recognize the complexity of culture diversity and its ongoing evolution as individuals live their cultures (Rogoff, 2011). This means we must avoid putting the children and students we serve as educators in “boxes” that are not relevant in guiding our perceptions and actions. In any cultural box that we name, “Hispanic,” “African American,” “Asian,” “Native American,” and so on, a wide variety of students so identified do not belong in the “box.” The diversity that we observe in these children and students is what makes them who they are and what should drive us in our teaching and learning endeavors.

- Since the publication of *Children’s Play in Diverse Cultures* (Roopnarine, Johnson, & Hooper, 1994) more than 2 decades ago, our understanding of the ethos of childhood, childhood activities, and early childhood education in different cultural communities around the world has increased significantly. Witness, for example, the growing number of volumes dedicated to the cultural basis of human development and early education in different regions of the world. In the area of children’s play, three relatively new journals (*International Journal of Play*, *American Journal of Play*, and *Journal of Playwork Practice*) and the Association for the Study of Play volumes have all made concerted efforts to publish research on children’s play and play-like activities in cultural communities at different levels of economic and technological development.
- These advances have no doubt occurred as a result of the push within social science and educational disciplines and subdisciplines for more indigenous perspectives on childhood development and for greater integration of scientific knowledge on children’s play from different regions of the

CULTURAL VARIATIONS IN PLAY

world (see Roopnarine, Patte, Johnson, & Kushner, 2015). This entry presents a selective overview of children's play in diverse cultural settings. It focuses on three primary issues: (1) conceptual considerations, (2) parental beliefs about play, and (3) variations in the meaning of children's play in cultural settings.

Conceptual Considerations

Traditional cognitive and social development theories and frameworks on children's play, including those by Jean Piaget, Mildred Parten, and Sara Smilansky, and, by extension, definitions of play have been instrumental in laying the foundation for much of the research and discussions on play and childhood development in North America, Europe, and, to a limited extent, cultural communities in other parts of the world. Whereas these established frameworks have played a seminal role in guiding our understanding of play and development generally, the cultural bases and properties of children's play in the developing world have been a minimal part of larger intellectual efforts and discourses.

Today the fields of child development and early childhood education are faced with the challenge of addressing play and development in a global community influenced by remote acculturation, changing childrearing practices, revisions of national early childhood education goals and objectives in a number of societies, greater numbers of manufactured toys and objects, reduction of play spaces, internal and external population mobility across societies, and greater awareness of the rights of children. In view of the complexities of these issues, play research and practice would be greatly enhanced by further considerations of the cultural properties of childrearing and conditions within the immediate ecological niches that influence their expressions. Put differently, there are diverse cultural pathways between play and early development, and factors within ecological niches assume a pivotal role in influencing such pathways.

The links between play and play-like activities and childhood development are likely mediated via

the beliefs and socialization processes embraced by particular cultural groups. This position is rooted in the frameworks of Lev Vygotsky, Beatrice Whiting and John W. M. Whiting, and Charles M. Super and Sara Harkness, all of which emphasize the contextual aspects of childhood activities and development.

In particular, Whiting and Whiting (1975) identified environment and history, maintenance systems (e.g., subsistence patterns, modes of production), learning environments of the child (e.g., settings, caregivers), behavioral tendencies and beliefs of the adult, and projective-expressive systems (e.g., religion and ideology) in shaping parental behaviors and childhood outcomes. Adding to these contextual issues, other frameworks such as colorism, critical race theory, and anti-colonial theory have aided our understanding of developmental patterns in historically oppressed groups (e.g., African Americans, indigenous groups, formerly colonized groups). These latter frameworks underscore changes that have occurred in parenting practices and children's play over time in certain cultures as a result of transplantation, loss of natal cultural practices, and dominance and resistance (Escayg, 2014). They are mentioned here in an effort to help build a pan-cultural understanding of play and development inclusive of the experiences of a sizable number of children who live under difficult social-political and economic circumstances.

Parental Beliefs About Play

Parental beliefs or ethnotheories about childrearing and childhood development guide the introduction and structuring of social and cognitive experiences for children. These beliefs or ethnotheories represent cultural ways of knowing and doing things, and they vary a good deal by ethnicity/cultural groups and sociodemographic characteristics. For example, cultural variations exist in the age at which parents expect children to acquire common developmental milestones, begin rigorous early academic training, and display courtesy, obedience, and respect. Different expectations and

understandings about play and its role in cognitive and social development in young children are also evident across cultural communities.

It has been argued that beliefs about the benefits of play can be placed along a continuum. Economically privileged groups (e.g., Europeans, European Americans) who see play as a developmental asset for the acquisition of basic cognitive and social skills necessary for preparation for entry into formal schooling are at one end. In fact, some have gone so far as to suggest that play stimulation is a modern invention of White middle-class parents because of its rarity in other cultural groups (Lancy, 2007).

At the other extreme are many parents, mainly in the developing societies, who see play as a naturally occurring event in children with few, if any, connections to the development of childhood skills. For example, Yucatec Mayans view children's engagement in play activities as signaling that children are healthy and out of the way of adult activities; Indian mothers think children play naturally; Jamaican parents believe that early childhood settings are for academic work and the outdoors are for play; and Taiwanese mothers and Asian American mothers endorse play with academic materials but are unsure about the benefits of play in general. Migrant worker parents in the United States are often dismayed that children spend so much time playing in preschool, and Turkana pastoralists native to Kenya believe work takes precedence over playful activities as children age (see Roopnarine et al., 2015).

These belief systems indicate that parents often view early learning as occurring through mechanisms other than play activities. In particular, the Yucatec Mayan engage in what Gaskins calls open attention where children, when playing, "always have one foot in the play frame and one foot in the real world" (Gaskins, 2015, p. 13). According to Gaskins, they are expected to notice what is going on around them even as they play. However, in several emerging economies, such as Turkey and Brazil, better educated families are beginning to endorse play as a means to learning cognitive and social skills (Ivrendi & Isikoglu, 2010; Vieira et al., 2010).

Newer attitudes about the benefits of play in these emerging economies may be connected to (a) movement away from traditional approaches to childrearing (e.g., unilateral obedience, total interdependence) toward more child-centered approaches that value both autonomy and interdependence, (b) the presumed benefits of early education and play stimulation in staving off the effects of poverty and challenging home and neighborhood environments, and (c) a greater emphasis on the rights of children worldwide.

Cultural Practices and Parent-Child Play

Socialization beliefs and practices are the drivers behind the nature and quality of play activities that parents engage in with young children. Data from two studies provide adequate support for this proposition. In a comparative analysis of parent-child interaction, Keller, Borke, Chaudhary, Lamm, and Kleis (2010) assessed family allocentrism (e.g., family cohesion) socialization goals (autonomous, relational) and mother-infant play in New Delhi, India, and Berlin, Germany. Consistent with beliefs and practices in both cultural communities, Indian mothers scored higher on allocentrism (e.g., family cohesion, closeness) and expressed more relational socialization goals (e.g., close social ties), whereas German mothers expressed more autonomous goals (e.g., independence striving). It appeared that these childrearing beliefs and practices affected the types of play activities the two groups of mothers engaged in with their infants. Indian mothers engaged in less distal parenting (more touching and holding) and more didactic play. German mothers promoted more autonomous play (child's initiative for play, respect for autonomy, supportive approach to play). However, the two groups did not differ in face-to-face contact and play with objects.

Research conducted in English-speaking Caribbean countries also suggests parallels between childrearing and childhood development, but in a slightly different way. Caribbean parents place a high premium on facilitating academic preparation, learning manners, and being obedient to

adults. Not surprisingly, when parents were asked about the most important things children should learn in preschool, they indicated writing and spelling their names, recognizing the letters of the alphabet and accompanying sounds, number recognition, and counting (Leo-Rhynie et al., 2009). These expectations were reflected in classroom practices and teachers' ratings of children's involvement of play activities in early childhood classroom settings. In preschools in both Guyana and in Trinidad and Tobago, children's engagement in artistic expression, symbolic play, cooperative play, and creative imagination were in the moderate to low range. Play is simply not emphasized as a viable way of learning early academic skills in Caribbean communities.

Variations in Children's Play

That children play in diverse ways (e.g., combining work with play, exploring the realms of the play world and reality, using natural materials) and in diverse settings (e.g., seaside communities and inland rivers in Brazil, riverbed communities in Kenya, structured agencies in Taiwan) across cultures has long been established. What is of importance here is the pan-cultural value that can be applied to play. The growing body of work on children's play in different cultural communities points to three salient issues: (1) The physical setting or ecological niche can impose limits on but also provides numerous opportunities for children to play in diverse ways; (2) parental belief systems or ethnotheories govern or, at the very least, shape the types of play and play-like activities children engage in across settings; and (3) the changing dynamics of childrearing worldwide seem to affect where and how children play.

Whether in the seaside communities of Brazil or the dry riverbeds in Kenya, seasonal changes and materials available to children within the natural environment alter their play considerably. Among several cultural groups, because parents see play as an integral part of childhood, systematic attempts to stimulate children through play are rare and may even be viewed as odd. But the single most important factor bringing into sharp focus the role

of play in childhood development is the changing nature of childrearing and expectations of children in a globalized world.

Implications for Early Childhood Development

The promise of play as a learning mechanism for the acquisition of academic and social skills is gaining traction worldwide. However, the degree to which this promise is embraced and implemented within homes and early childhood classrooms outside of the developed world remains sketchy. There is some agreement among early childhood researchers that play and play-like activities offer one of many avenues (others being direct observation and participation in adult-like activities or apprenticeship-like activities) for children to acquire the skills necessary for life within a particular cultural community. Play as a construct for learning is witnessed in the replication of adult activities by young children in a variety of settings (such as camel herding in the pastoralist Turkana or the daily activities of the Parakana Indians of Brazil). Nevertheless, the direct connection between play and learning is less well understood in the developing world. We propose that play provides a context for the qualitative expressions of wide-ranging activities that are directly or indirectly related to aspects of childhood development through different cultural pathways.

CURIOSITY

Curiosity is often given great importance in early childhood and is included in educational and curricular standards, such as those developed by the National Association for the Education of Young

Children and American Association for the Advancement of Science. It is also discussed in federal legislation such as the No Child Left Behind Act. Teachers choose it as one of the top five skills or traits children need for school success and place it above counting ability and letter awareness as predictive of school readiness.

Despite this perceived importance and the unchallenged belief that curiosity is critically important for learning and motivation, little is known about curiosity in early childhood education. This lack of understanding is perhaps due to the difficulty in defining curiosity and the equally challenging task of designing ways to measure children's curiosity. This entry discusses how curiosity has been defined and measured in research and what is known about the relationship between curiosity and learning.

Research on Curiosity

Daniel Berlyne defines curiosity as the desire to alleviate a feeling of missing or inadequate information, resulting in “specific exploration” to find that information. *Epistemic curiosity* is exploration that goes beyond providing a means to gaining missing information to include the desire to acquire knowledge. Like many psychological constructs, curiosity can be both a stable personality characteristic and a state influenced by environmental factors. Educational programs suggest the importance of both utilizing children's curiosity (more trait-focused) and fostering curiosity (more state-focused).

Research on curiosity also differentiates between curiosity as a state and trait in its measurement. The majority of research on adults uses questionnaire scales intended to assess curiosity as a trait, asking how people feel about things in general. Some, though, focus on how curious adults are across different situations, using prompts about how curious people feel in specific instances or scenarios.

In children, curiosity has been studied using both questionnaire and behavioral observation measures. In a series of studies, Wallace and Ethel Maw used rating scales to assess children's curiosity. Teachers and/or parents ranked children's curiosity

using a detailed definition with descriptions of a curious child, such as one who demonstrates the desire to learn, persists in exploratory behavior, and reacts positively toward and seeks out new or strange things. Peer ratings and self-ratings were also used, with children matching their classmates and themselves to a series of vignettes about more and less curious children. Curiosity was found to relate to learning behaviors such as attention and persistence, but also IQ—perhaps because of teachers' difficulty differentiating curiosity from more general scholastic aptitude, confounding the measure. Self-report measures have additional limitations in developmental research; they rely on reading or verbal comprehension abilities and are less engaging than behavioral measures. Thus, direct measures of exploratory behavior have been the preferred method for developmental research.

Behavioral measures for young children tend to fall into three broad categories: (1) curiosity as spontaneous exploration, (2) curiosity as exploratory preference, and (3) curiosity as preference for unknown and uncertainty. These categories are not exclusive; rather, they are somewhat organized from broadest to narrowest, and the focus switches from being on solely the *amount* of exploration, to *what* is explored, to the *interaction* between a child's knowledge and the characteristics of an object or event.

In assessments of spontaneous exploration, children are observed playing either with toys or in a stimulating environment, and frequency of physical manipulations and/or verbal observations and questions provide a curiosity score. While this method of measurement involves natural exploratory behavior, it ignores several factors of the stimuli and activity—for example, children might have different levels of familiarity with the toys or environment, which leads to different interactions, and some choices might be more appealing or interesting to some children or have differences in possible manipulations. It is also unclear whether these measures give an indication of more stable or more state-dependent curiosity, as they do not indicate whether children would similarly explore across situations or whether

behavior was dependent on the specific materials provided.

Some of these issues can be addressed by shifting the focus to specific characteristics prompting exploration. Curiosity as exploratory preference involves how likely a child is to explore based on an object or event's characteristics. When curiosity was assessed using figures and toys varying in novelty, complexity, incongruence, or conceptual conflict (e.g., an animal with mismatched parts), children preferred looking at and playing with more novel, complex, incongruent, and conflicting stimuli, though there was high variability, suggesting individual differences. This research suggests that designing these types of materials and opportunities for learning can motivate curiosity. Studies also suggest the relationship is not linear, that these characteristics increase exploration only to a point, at which the likelihood of exploration begins to decrease again, and this point may not be universal for all children.

The third operationalization of curiosity—preference for uncertainty or ambiguity—focuses less on the characteristics of objects or events themselves and more on the relationship between them and a person's existing knowledge. A toy does not have to be new or complex, but the children feel they do not know something about it and thus feel a desire to find the unknown information. For example, children were more motivated on a task when it related to their ability to find something out, and they preferred to explore most when faced with surprising, uncertain, or ambiguous information, even when the alternate choice was novel.

George Loewenstein's information gap theory of curiosity explains these results by suggesting that curiosity results from a person's realization of a gap in his or her current knowledge state and the perceived ability to acquire the information to fill the gap. To study information gaps in adults, researchers asked adults to rate their feeling-of-knowing on items (e.g., don't know, know, or tip-of-tongue [TOT], when participants felt they knew but couldn't retrieve the information). The highest levels of curiosity and exploratory behavior were reported for TOT-producing items.

Jamie Jirout found a similar pattern in young children's exploration of information gaps by experimentally manipulating the amount of information given to children to create differing information gaps in an exploration game. However, she also noticed variability in the strength of preferences for both children within the same task version and those with varying amounts of uncertainty. Children's "uncertainty preference"—a more stable characteristic—was assessed with a computer program with an algorithm to present exploration choices differing in uncertainty based on children's exploratory behavior. Although most children become curious when presented with *some* uncertainty, the level most likely to lead to individual children's exploratory behavior varied. Research assessing issues of reliability and validity of this measure and the measures of curiosity as a state continue to be developed, but their use has yielded some knowledge about children's curiosity in education.

Curiosity in the Classroom

Is curiosity related to learning? Do more curious children learn more, and are learning opportunities that promote curiosity more effective? Examining the relationship between curiosity and learning is difficult. The literature on curiosity is inconsistent in how curiosity is defined and measured, so findings cannot be generalized across studies. In studies of curiosity as a stable, individual differences variable, the link between curiosity and learning can only be assessed as correlational. The relationship between general IQ or ability and curiosity has inconsistent findings, and only a few studies have looked at curiosity and *learning*.

In one such study, children differing in curiosity level did not display different exploration patterns while playing in a museum exhibit, but curiosity did relate to how much children learned, with more curious children learning more from their play. Similar findings were observed in a study of learning from exploration of a virtual museum, in which highly curious children were found to learn more than less curious children. In a study of learning in a more structured setting, no differences in

learning from a question-asking intervention were found between children who were more or less curious, although the more curious children asked more questions in general and were better able to identify *effective* questions, and asking and recognizing effective questions are skills that could lead to learning. Children have been found to learn better from self-generated questions than textbook- or other-generated questions, perhaps from self-explanation and having to identify a knowledge gap and articulate it with a question.

When looking at curiosity as a state, children can be made more or less curious by introducing information gaps. There is some evidence that this leads to learning. In a study of children's causal reasoning, children saw either unambiguous or ambiguous demonstrations of the causal function of a toy. When they saw ambiguous demonstrations, children were more likely to choose to explore the demonstrated toy than a novel one, which was chosen more often after unambiguous demonstration of the causal functions of the toy.

In another study investigating the influence of instructional constraints on exploration, children interacted with a toy with four possible functions. When shown one of its functions (and, not knowing about the other functions, having no uncertainty about how the toy worked), children explored and discovered fewer other functions than after no demonstration or a demonstration that was perceived as incomplete. Children may have been more motivated to explore multiple functions with no demonstration or an incomplete demonstration because they didn't understand how the toy worked, creating a gap in knowledge. The same pattern of results was observed for physical exploration of a noncausal task and with a digital exploration game, on which children were more engaged and motivated although learning was not assessed.

More work is needed to understand what makes children curious and how to address different individual levels of curiosity in education, although the state-curiosity research provides clear suggestions for how to promote children's curiosity. Helping children to recognize a gap in their knowledge can lead to increased effective exploration and question

asking, activities related to learning. For example, having children generate their own questions can help them identify what they know and do not know. Demonstrations that are surprising or have unexpected outcomes can lead to exploration, and introducing uncertainty using “cognitive conflict,” or a contradiction with a child’s existing knowledge, leads to both conceptual change and generalization of learned concepts, as well as making a learning activity more motivating. However, when designing these activities, determining how much uncertainty is “too much” is difficult, especially with individual differences in preferred uncertainty.

Amanda Markay and Loewenstein suggest that of crucial importance for curiosity and learning is providing a welcoming and supportive environment where exploration is encouraged, as well as answering children’s questions directly or assisting them in answering their own questions—and to not get in the way of exploration. Fortunately, children can be seen expressing curiosity even when conditions may not be very supportive. With the freedom to explore, the resources needed, confidence in their ability to find desired information, and guidance or scaffolding when needed, their curiosity will hopefully lead to learning.

CURRICULUM AND EARLY CHILDHOOD EDUCATION

This entry begins by defining curriculum, then looking at its special meaning in early childhood education. It defines stages of curriculum development, from a set of ideas, to a book, to demonstration programs, to an observational assessment tool, and distinguishes between evidence of the validity of independent curriculum practices and evidence of the validity of complete curriculum implementation in specific programs. It tracks the history of early childhood curriculum models, from Friedrich Froebel’s kindergarten, through the Montessori method, to the development of various curriculum models with the advent of the national Head Start program in the United States. It identifies several types of early childhood curriculum models, with the basic distinction being teacher-centered versus child-centered. It summarizes five well-developed, currently prevalent models—HighScope, The Creative Curriculum, Tools of the Mind, Reggio Emilia, and Montessori—then compares them and summarizes curriculum comparison studies.

Definition of Curriculum

Although curriculum is commonly defined as a course of study, a more useful definition is the planned interaction of pupils with instructional content, materials, resources, and processes for evaluation. Some equate curriculum solely with educational objectives for students, but this definition clearly embraces educational practices and even assessment practices. Indeed, one might simply define curriculum as what takes place in education.

In early childhood education, curriculum has taken on a second meaning, that of educational model. This was probably because early childhood education was not so strongly rooted in the educational traditions of schooling by teacher-directed instruction based on reading, writing, and arithmetic. The content and educational practices of early childhood education were more open to debate. Should the content focus only on literacy and mathematics, or should it extend to other aspects of children's learning and development, such as social and emotional skills and attitudes, habits of mind, and physical skills? Should educational practices focus on the transmission of knowledge from teacher to students, or should the teacher facilitate children's learning from their own activities? Early childhood curriculum developers take various positions on these issues and develop curriculum models representing these positions.

Stages of Curriculum Development

A curriculum model may be seen as a set of ideas describing how an educational program should work. This set of ideas may be published in a book or set of books or audiovisual materials. Successive editions of these materials translate into successive editions of the curriculum model, which are meant to keep up with changing contexts and perhaps apply new research findings or ideas to the model. It is possible for various writers to represent the same curriculum model in different ways. To resolve such discrepancies, one person or body needs to have the ultimate authority for designating what constitutes accurate representation of the curriculum model.

Viewing a curriculum model as residing in operating programs leads immediately to the question of which operating programs accurately represent the model. There might be a flagship classroom so designated, or, in the case of the Reggio Emilia approach, early childhood programs in a particular city. But just as human beings do not always live up to their ideals, so do teachers not always faithfully represent a curriculum model.

A third option is to have an assessment tool that defines and decides what constitutes best expressions of the curriculum model—which practices are correct or desirable and which are incorrect or undesirable, which practices are better than other practices. HighScope developed the Program Quality Assessment for this purpose. Similar instruments, such as the Early Childhood Environment Rating Scale and the Classroom Assessment Scoring System (CLASS), are not identified with a specific curriculum model and cannot be used for this purpose without further development or interpretation.

A curriculum model goes through various stages of development, some models advancing further than others. First comes the basic curriculum ideas or principles, articulated in some form. Next comes a more complete written description of the curriculum model—its principles, practices, goals, and objectives. The curriculum model must be put into practice during this initial period for the development of the ideas to take place. Because the worth of education comes from its contribution to children's development, it is desirable for research to be conducted along the way to determine (a) whether the model's principles and practices can be found in observable practice, and (b) whether the model's goals and objectives for children's development are achieved when its principles and practices are followed.

A curriculum can be evidence-based in two ways. One is that its principles and practices come from early childhood development and education research findings and theory. The other way is that the curriculum as a whole has been validated by research, that is, whether there is evidence that its principles and practices have been observed and

verified in real programs and whether these programs achieve their goals and objectives in children's development.

Brief History of Curriculum in Early Childhood Education

Traditionally, schools for children have grades, one for each year of age, with first grade—the beginning of traditional schooling—set at around age 6 throughout the world. Presumably, age 6 acquired this status as the time to begin to learn to read, write, and do arithmetic, the basis of traditional schooling. This definition of first grade underlies the development of early childhood curriculum as distinct from traditional schooling and open to the ideas of curriculum developers.

Froebel invented the idea of kindergarten, a garden for children, and developed what might be regarded as the first early childhood curriculum model in 1837 in Germany. Whereas others saw little value in children's play, Froebel made it the centerpiece of the kindergarten curriculum and saw it as the way to prepare for the intellectual learning to come later. He developed materials he called "gifts" (cubes, balls, and tablets) and "occupations" (materials for writing, drawing, and painting) and identified activities for children (games, songs, and stories). After Froebel, the next early childhood curriculum model came with Montessori in 1907 and then not until a flurry of models developed with Head Start in the United States beginning in 1965.

Head Start's position on early childhood curriculum is critical not only because it is the largest well-defined early childhood program in the United States but also because it influences many other programs. The 1998 reauthorization of Head Start requires each agency to have a curriculum, that is, a written plan that is based on sound child development principles; is consistent with Head Start Program Performance Standards overall; and includes goals for children's development and learning, experiences, staff and parent roles, and materials. The 2007 reauthorization requires each agency to implement an early childhood curriculum that promotes young children's school readiness, is

based on valid research and has standardized training procedures and curriculum materials, is comprehensive and linked to ongoing assessment, focuses on improving the learning environment, and is aligned with the Head Start Child Development and Early Learning framework.

Types of Curriculum Models

Early childhood curriculum models are often divided into whether educational activity centers on the teacher or the child. In a teacher-centered model, the teacher defines the educational activity by lecturing, speaking every other turn in a question-and-answer discussion, and assigning seat work. In a child-centered model, the child defines the educational activity by choosing or planning activities and their components. These terms are open to various interpretations, and it is easy to make either of them so extreme as to be dismissed. Most early childhood curriculum models fit somewhere on the continuum from purely teacher-centered to purely child-centered.

Alternative classification frameworks offer additional curriculum types. Parenting styles have been characterized as authoritarian (adult-centered), laissez-faire (child-centered), and authoritative. David Weikart, who led the early development of the HighScope Curriculum, developed a 2 × 2 matrix, laying out high and low degrees of teacher direction and high and low degrees of child initiation. Direct instruction involves a high degree of teacher direction and a low degree of child initiation. Traditional nursery school involves a low degree of teacher direction and a high degree of child initiation. Custodial care involves a low degree of teacher direction and a low degree of child initiation. HighScope and other developmental interaction models involve a high degree of teacher direction and a high degree of child initiation.

How Practitioners Relate to Curriculum Models

Early childhood practitioners relate to curriculum models in various ways. Some identify a curriculum model as their own and strive to follow it

exactly or to the extent possible, as advocated by Head Start. Others identify one or more curriculum models that influence them to some extent, following some but not all of the practices that define these models. Others see themselves as developing their own curriculum, possibly adapting some practices from various models or deriving practices from child development theories. Others do not follow a curriculum model and may not even see themselves as developing one. They may see government or professional standards as sufficient for the purpose of a curriculum model. However, curriculum models are part of early childhood education culture and influence all early childhood educators to some extent, whatever their position on adopting specific curriculum models. This influence makes it impossible to isolate the effects of a curriculum model from early childhood programs not using the model at all.

Some Leading Curriculum Models

The sixth edition of *Approaches to Early Childhood Education* (2013) has chapters on nine curriculum models, five from the United States and four from Europe. According to Jaipaul Roopnarine, one of the editors, the editors selected these models based on four factors: (1) external reviews solicited by the publisher; (2) the editors' reading of the most appropriate advances in the early childhood education field (e.g., cultural, developmental, theoretical); (3) research substantiation, ease of application, and appeal to early childhood education professionals; and (4) general feedback on the volume from early childhood professors, students, and practitioners across disciplines and geographic locations. The U.S. models are The Creative Curriculum, HighScope, Tools of the Mind, Bank Street's developmental interaction, and the project approach. The European models are the Piramide approach, Reggio Emilia, Montessori, and Waldorf.

The 2013–2014 Head Start Program Information Report offers early childhood curriculum alternatives for center-based services, family child care services, and home-based services. These alternatives are rooted in HighScope, The Creative

Curriculum, DLM (Developmental Learning Materials), High Reach, Domains Based Curriculum (Core Knowledge), Innovations, Scholastic Early Childhood Program, Parents as Teachers, Growing Great Kids, and Florida State University's Partners for a Healthy Baby. These alternatives were offered because of their prevalence in previous Head Start Program information reports, collected annually from Head Start directors throughout the United States.

Brief summaries of some of these curriculum models follow, focusing on those that are more fully developed, validated, and prevalent in the United States. This entry summarizes HighScope, The Creative Curriculum, Tools of the Mind, Reggio Emilia, and Montessori. This encyclopedia includes entries on these and other early childhood curriculum models that elaborate on these summaries.

HighScope Curriculum

The HighScope Curriculum is a system for adults to support children's active learning and development. David Weikart (1931–2003) and his colleagues developed the HighScope Curriculum for use in the Perry Preschool program and first published it for general use in 1971. HighScope has developed and spread its educational model for young children in preschool programs, infants and toddlers in home visit programs and child care settings, children in elementary schools, and teenagers in summer camps and after-school programs.

The HighScope Preschool Curriculum for children 3 to 5 years old starts with a strong commitment to young children as thinking, responsible human beings. Adults ask children what they want to do and help them develop essential knowledge and skills based on the children's own interests. They provide open-ended materials and interact with children to support their exploration and extend their learning. They arrange the classroom into activity areas to support various kinds of learning. They establish a daily routine that allows children to plan, carry out, and review their own learning activities. They focus on key indicators of all aspects of children's development. Teachers work with parents to apply curriculum principles

and practices with children at home. Teachers assess program quality with HighScope's Program Quality Assessment and assess children's development using the Child Observation Record.

Research support for the HighScope Curriculum comes from various studies. One study found that program participants are better prepared for school and have better long-term outcomes educationally, economically, and in crime reduction, thereby providing a substantial public economic return. Another study found that the HighScope Curriculum leads to substantial improvement in young children's intellectual performance and does better than a fast-paced direct instruction program in preventing emotional impairment or disturbance during schooling and serious crime in young adulthood. Another study found that classrooms with HighScope-trained teachers significantly surpass comparison classrooms on a range of supervisory and teaching practices, and children in HighScope programs do better than their non-HighScope peers in most aspects of their development.

HighScope has developed curriculum materials for parents and caregivers of infants and toddlers. The adults form loving, trusting relationships with the babies and toddlers in their care. As with older children, the approach focuses on children learning through direct, hands-on experiences with people, objects, events, and ideas. The curriculum offers proven teaching practices that support children's development, content areas for infants and toddlers, program and child development assessment tools, and a training model that helps parents, teachers, and caregivers implement the curriculum effectively.

HighScope offers various active-learning training options tailored to the needs of teachers and caregivers serving infants, toddlers, and preschoolers in all types of settings. HighScope training-of-trainers programs give early childhood program organizations anywhere the independent capacity to provide HighScope teacher training. These programs have enabled the establishment of teacher education institutes and centers in Canada, Chile, China, Great Britain, Indonesia, Ireland, Korea, Mexico, the Netherlands, Portugal, and

South Africa. HighScope has also recently provided training in Dubai, Saudi Arabia, the Caribbean, and elsewhere.

The Creative Curriculum

The Creative Curriculum is now in its fifth edition, focused on its foundation; its 10 interest areas for children, literacy, mathematics; and its objectives for child development and learning from birth through kindergarten. Diane Trister Dodge is the original developer. The model's roots are in the early years of Head Start in the 1960s, with a modest first edition coming out in 1978. It offers a complete system of resources that supports teachers at all levels of experience. The fifth edition is fully bilingual and meant to include dual language learners, children with disabilities, and children with advanced knowledge and skills.

The Creative Curriculum is based on the work of theories of Jean Piaget and Erik Erikson, research evidence, and the positions of the National Association for the Education of Young Children, especially on cultural sensitivity. Its foundational principles identify five contributors to children's successful development—positive interactions and relationships, socioemotional competence, constructive and purposeful play, learning interactions in the physical environment, and teacher–family partnerships. It has versions for preschool, infant-toddler care, and family child care. Each has a five-sided framework focused on how children develop and learn (socioemotional, physical, language, cognitive); the learning environment (interest areas, daily and weekly schedules); what children learn; caring and teaching; and partnerships with families. At the center of this framework are routines and experiences of various types. It rests on theory and research.

The Creative Curriculum and its child assessment Teaching Strategies GOLD have 38 objectives for development and learning within 10 domains. Each has 10 levels of difficulty defined at every other level of the objective. The assessment cycle comprises observing and collecting facts; analyzing and responding to them; evaluating

them; and summarizing, planning, and communicating them.

In addition to the curriculum volumes and Teaching Strategies GOLD, Teaching Strategies provides teaching guides focused on “studies” by children, intentional teaching cards, resources for read-alouds, and “Mighty Minutes” (100 small cards describing brief activities). These resources are intended to support professional development activities.

A study of The Creative Curriculum by Philliber Research Associates in 2004 found that training in it led to greater-than-expected gains in children’s school readiness. Several other studies are under way. Teaching Strategies GOLD was field tested and normed in 2009. In the Head Start FACES (Family and Child Experiences) study of 2006, 64% of Head Start teachers reported using The Creative Curriculum as their primary curriculum. It is also used in all military child care programs. In 2009 it was approved for use in 19 states that approve early childhood curricula for use. It is studied in many college courses.

Tools of the Mind

Tools of the Mind is an early childhood curriculum developed by Deborah Leong and Elena Bodrova following the child development theory of Lev Vygotsky (1896–1934). Vygotsky took a cultural-historical approach, bringing together individual and human history, and focused on applying the cultural tools of signs and symbols in children’s higher mental functions, that is, the tools of the mind. These higher mental functions, such as learning and teaching, deliberate memory, and logical teaching, fundamentally reorganize lower mental functions, such as reflexes, perceptions, associative memories, reactive attention, and sensorimotor intelligence. The major goal of education is to help children acquire the tools of the culture. Children shift over time from dominant lower mental functions to dominant higher mental functions.

Vygotsky’s general law of cultural development is that it goes from shared to individual, in contrast

with Piaget’s focus on individual child development. Development results from the complex interplay of the biological and the social. Learning can lead development, when it is in the child’s zone of proximal development, in which assisted development precedes and facilitates individual development. Teachers and children co-construct knowledge. Construction of knowledge takes place in a social setting. The teacher’s job is to supply the right materials and direct children’s attention. The teacher scaffolds children’s development from assisted to independent. Instruction amplifies but does not accelerate children’s development. The child’s social situation is the main mechanism of his or her development. Leading activities of development result in developmental accomplishments. The four stages of children’s development are infancy, toddlerhood, preschool/kindergarten, and elementary. School readiness develops in the first months of schooling, not before.

Early childhood teachers engage children in leading activities of development, largely by supporting their make-believe play. Such play should lead them to develop higher mental functions and cultural tools, not the full range of skills and concepts. The desired play is specifically make-believe play, not object manipulation, games, or sports. In make-believe play, children create imaginary situations, take on and act out roles, and follow the rules that comprise these roles; in this curriculum, they make play plans. Such play is not spontaneous, as the word is sometimes understood; rather, it helps children develop self-regulation and abstract thinking. They develop the mental tools of private speech and written speech, which evolve from pictures they draw and stories they tell.

From a Vygotskian perspective, special education is about re-mediation. Children have special needs primarily because of their sociocultural development rather than their biological development. Their lower mental functions have not reorganized properly into higher mental functions, so these higher mental functions develop as secondary disabilities and require re-mediation.

Several experimental studies involving random assignment of children to Tools of the Mind or

other preschool curricula have been conducted. Some have found effects on self-regulation and achievement and others have not.

Reggio Emilia

Reggio Emilia is a town in Italy (2010 population 168,883) that has an extraordinary tradition of social commitment to the development of its young children in supportive families. In 1968 Italy recognized the right of all children to high-quality early childhood education, subsequently developing maternal schools for infants, toddlers, and preprimary children. Teachers stay with the same groups of children while they are in a 3-year preprimary or 6-year primary school. Loris Malaguzzi (1920–1994) led the Reggio Emilia effort. He believed that custodial care and typical schooling dulled children's intelligence and that there was a better way. He saw theory coming from practice rather than theory driving practice. At that time, preservice teacher education was not required so Reggio Emilia developed in-service teacher education that involved documentation of children's activities, transitioning of children, and family involvement. The schools hired artists or art educators to help children express themselves. By the 1980s, Reggio Emilia sponsored traveling expeditions of children's work around the world.

The Reggio Emilia approach is based on three principles: (1) Acknowledge children's creative, intellectual, and communicative potentials; (2) schools are relationship systems: children's well-being comes from the well-being of teachers and families; and (3) doubt and uncertainty are reasons for teachers to learn about and with the children they teach. The school is a place for learning through relations, rather than a program; the curriculum comes from documentation of children's curiosities; and parents are educational partners. The physical space is very important to education—large central space, abundant materials, natural lighting, plants, like an Italian piazza. The space communicates the idea that each activity is important, for example, displaying photographs and artwork of children.

The curriculum has no stated goals or lesson plans but rather creates the conditions for asking and exploring good questions. Malaguzzi believed that children are capable of more than usually expected, and their work in Reggio classrooms shows that. Two teachers per classroom collaborate, meeting 4 to 6 hours a week for this purpose. Families help make school decisions, from menus to admissions policies.

Today Italy requires infant-toddler providers to have 3 years of college education and teachers of 3- to 11-year-olds to have 5 years of college education. Reggio Emilia has an age 3 to Grade 2 school; it has found success in bridging early childhood and education cultures with academically oriented art projects. Ten percent of Italy's population are now immigrants, and Reggio Emilia has embraced this challenge, showing it can serve them as well as upper middle class children.

The Reggio Emilia approach arrived in the United States along with new research on brain development, and in some ways its approach aligned with the findings of that research. It offered a new way of seeing developmentally appropriate practice. It got good press among early childhood educators and parents. But the achievement test emphasis in the United States in recent years refocused much of early childhood education and challenged the Reggio Emilia way of thinking, raising the question of whether the promise of the Reggio Emilia way of thinking in the United States is real or imaginary.

Montessori

Maria Montessori (1870–1952), Italy's first female physician, opened a Children's House for 4- to 7-year-olds in a lower income housing project in Rome in 1907. Her educational beliefs and values challenged educational tradition—belief in the power of early childhood experience versus fixed intelligence; valuing of intrinsic over extrinsic motivation and sensory experience over behavior and test performance; the view that the teacher is a facilitator and guide rather than the sole source of knowledge for children. Interest in Montessori

resurged in the United States in the late 1950s, first in private schools founded by middle-class parents, then in public schools. Membership in the American Montessori Society or the Association Montessori Internationale is voluntary, and most of the 5,000 Montessori schools in the United States today do not belong.

The Montessori method has five principles:

1. Children are grouped over 3 years of age, 3 to 5 or 6 to 8.
2. Classrooms have tables and desks arranged for individual and small group work, with accessible materials on low shelves, one of each item per child, and open floor space.
3. Children engage in individual and small group work 3 to 4 hours a day and no more than an hour of whole group work.
4. Children are encouraged to cooperate rather than compete. Answers to questions are easily available. Government-required tests are given but are considered of little importance. Instead, teachers rely on careful observation of children in their activities; they are to “follow the child,” as Montessori said.
5. Children are expected to be responsible for materials they use and to clean up after they use them.

A Montessori classroom is a prepared environment, in which the teacher sets a calm tone and matches children to high-quality materials and real, working, child-sized tools. Children want the freedom to do things themselves, leading to development of self-discipline. They have predictable routines. Classrooms have plants and gardens and are clean, colorful, and harmonious. They include but are not limited to Montessori didactic materials, such as the pink tower of cubes and cylinder blocks, which are used in one correct way and are self-correcting so children can use them independently. The teacher is a scientific pedagogue who observes children, redirects disorderly ones, presents brief lessons on how to use didactic materials that

interest children, lets children use materials to learn actively, leads large groups, keeps records, and stays in touch with parents. Community life and interaction are encouraged and supported. Curriculum areas include practical life, sensorial materials, language, mathematics, music, art, and drama, and cultural subjects such as geography and science.

In some 100 studies of Montessori education, selection bias is a common problem, in which curriculum effects cannot be distinguished from background differences between Montessori children and comparison children. Studies have small samples of children, don't last very long, and lack specificity about curriculum implementation. But it appears, at least in some studies, that Montessori children surpass others in language and mathematics achievement and school attitudes.

Comparisons of Early Childhood Curriculum Models

Whereas all of these curriculum models focus on children's development, strive to be developmentally appropriate, and are more child-centered than traditional schooling is, they were each developed by a different curriculum development group and have their own histories. All provide publications, audiovisual materials, and websites, but they differ in how much teacher support they provide. These curriculum models were developed throughout the 20th century, from Montessori in 1907 to Tools of the Mind in 1993. They vary in how they have addressed curriculum validation: HighScope and Tools of the Mind have received the most rigorous evaluations. Montessori practitioners have generated many studies, and The Creative Curriculum has several. Reggio Emilia sees rigorous evaluation as missing the most important aspects of education, a concern shared to some extent by all these models.

The models have various distinguishing features. Montessori downplays fantasy play, whereas Tools of the Mind emphasizes it. HighScope features the plan-do-review process and key developmental indicators. Reggio Emilia emphasizes children's

artistic expression. The Creative Curriculum focuses on positive relationships and purposeful play.

Early childhood curriculum comparison research began with Head Start in the 1960s. Concern about sustaining Head Start effects led to the federal Project Follow Through for kindergarten through third grade. Both Head Start and Follow Through engaged in planned variation of curriculum models, looking at the effects of various curriculum models. Such large-scale research readily reveals the limitations of design and measurement that make it difficult to draw simple conclusions. The Planned Variation Head Start Project in 1969–1971 found similar cognitive effects across various models and much variation within models across sites. Follow Through lasted from 1968 through 1995. Model effectiveness varied substantially from site to site. Models that focused on direct instruction in basic skills tended to build basic skills better than models that focused elsewhere.

Three experimentally designed longitudinal studies of early childhood curriculum models began in the 1960s—one at HighScope, another at the University of Louisville, and another at the University of Illinois. All three studies found that children in direct instruction programs outperformed children in traditional and other programs in intellectual performance during the program and up to a year afterward, but then this difference disappeared. In the only one of these studies that lasted to age 23, the HighScope group had numerous significant advantages over the direct instruction group, including fewer requiring treatment for emotional impairment or disturbance during schooling and fewer arrested for a felony or property crime.

From 2003 to 2007, the U.S. Department of Education funded a large study of 14 preschool curriculum models for children in low-income families. Each grantee implemented its curriculum and tested curriculum effects with randomized field trials against prevailing curricula in the schools. Eight of the 14 treatment curriculum models had a positive effect on prekindergarten classroom instruction, compared to their control curriculum models. Only one—DLM Early Childhood Express

supplemented by Open Court Reading Pre-K—had effects on children's language and literacy skills in the prekindergarten and kindergarten years. Pre-K Mathematics supplemented with DLM Early Childhood Express had effects on children's mathematics skills in the prekindergarten year only. Curiosity Corner and Early Literacy and Learning Model had effects in the kindergarten year but not in the prekindergarten year. The results of the study are disappointing. Perhaps pitting different models against each other on how much they contribute to children's literacy, mathematics, and social skills is not the best way to compare them.

DATA-BASED CHILD ADVOCACY

In recent decades a greater number of child advocates have begun using statistical data to improve the lives of children. At the same time more researchers and data analysts are using statistical data to provide a richer and more detailed understanding of children's lives. Combining data, statistics, and scientific evidence with efforts to improve the quality of life for children and youth is called *data-based child advocacy*.

This entry provides an overview of the emerging area of data-based child advocacy and describes why data-based advocacy is so important for children. It includes a list of activities that fall into the data-based child advocacy category and highlights the benefits of this new conceptual framework.

Background

The collection and use of statistical data and social indicators related to children has exploded in recent years. Measuring children's well-being is of growing importance to policy makers and people striving to improve the lives of children.

Data-based advocacy is more important for children in general and young children in particular than it is for other groups. Many groups trying to influence government policies and programs have significant political power because they can provide significant financial support for political

campaigns and influence how their members vote. Those with less political power, such as child advocates, must depend on an "outsider strategy," which includes appeals to the general public through research, press conferences, and use of media. Data are often critical for such efforts.

Data-based child advocacy may be more important for younger children than for older children. Older children (teenagers) often have the means to speak for themselves. In addition, researchers are able to use responses from older children to gather data on topics such as subjective well-being. Younger children typically are unable to voice their concerns and unable to respond to many researchers' questions. It is also worth noting that the youngest children are often the most disadvantaged. For example, children from birth to age 4 have higher poverty rates than any other age group.

Types of Advocacy Activity Using Child Indicators

Data-based child advocacy-related activities can be described and clustered many different ways. William O'Hare identifies six different kinds of data-based child advocacy activities (O'Hare, 2014b, p. 5):

1. Increasing public awareness about child well-being
2. Making data on children more easily available

3. Advocating for more and better data on children
4. Monitoring child well-being
5. Goal setting for child well-being
6. Evaluating programs and policies related to children

Many groups and scholars are already engaged in a lot of these types of activities, but it is seldom explicitly identified as advocacy. One of the obstacles to recognizing the use of child indicators in advocacy is the narrow view of advocacy. Carol De Vita, Rachel Mosher-Williams, and Nicholas Stengel (2001) state, "The term 'advocacy' is often considered synonymous with 'lobbying,' but such a narrow definition captures only one function in a much broader set of advocacy activities" (p. 4). Data-based child advocacy is often about elevating public understanding and awareness of problems and issues facing children rather than focusing on a specific piece of legislation or a specific policy.

Data-based child advocacy involves many different types of professionals and organizations from numerous arenas. It has been fostered and enhanced by work in philanthropy, international organizations, government agencies, civil society, nonprofit research organizations, and academia. It has involved a diverse mix of scholars, scientists, researchers, policy makers, journalists, advocates, and practitioners and many different scholarly disciplines (sociology, psychology, demography, social work, statistics, law, and public policy). This rich mix of providers and users often means this work does not fit neatly into existing conceptual frameworks.

Communication Issues

An Organisation for Economic Co-operation and Development publication highlights why communication is such an important topic for data-based child advocates: "When good statistics exist, they too often go unnoticed or misunderstood by a broad audience" (Giovannini, 2008, p. 14). Reaping the full benefits of data-based reports and research often requires strategic use of mass media.

Data-based child advocacy often requires that scholars and researchers communicate with public audiences who differ from scholarly audiences on two key points. First, academics and scholars typically read an article on children because they are already interested in the topic. Public audiences, on the other hand, are not necessarily interested in child well-being, so writers must capture their interest. Second, scholars and researchers are comfortable with science, statistics, and data, but a large segment of the public are unfamiliar with scientific principles and uncomfortable with statistics.

Integrating solid scientific evidence and statistical data with communication expertise is very important in terms of effectively reaching a mass audience. But this can be vexing to participants because there is a clash of cultures between data experts and communication experts. For example, scholarly writing almost always includes caveats and cautions about the results, but in writing intended for nonscholars, including a long list of caveats can be seen as undermining the veracity of the report.

Conclusions

Data-based child advocacy has been growing because it is an effective tool to help child advocates and researchers reach their goals of getting good data into the hands of users and improving child well-being.

DEFINING EARLY CHILDHOOD EDUCATION

An explosion of research over the past several decades offers much to learn about what is needed to support optimal development for young children. This entry first reviews the major understandings about development that inform and define early childhood education. It then describes key elements of high-quality early childhood education programs.

How Young Children Learn

From developmental psychology we have learned that active experiences are the trigger that enables children to organize their brains to support the challenges they meet. What this means is that during the early years of life, young children make sense of new concepts and ideas through active engagement with materials, ideas, and relationships. What adults often refer to as play—block play, dramatic play, singing, dancing, painting, drawing, and so forth—is really the work that children do to make sense out of the world. Jean-Jacques Rousseau, Jean Piaget, Lev Vygotsky, and others have theorized about this for some time, but recent developments in brain-based research have added other important dimensions to our knowledge.

Neuroscience's neuroimaging technologies have revealed how neural connections are formed and have confirmed that, during the early years of life, the development and collaboration of processing systems in the brain are enhanced by the play that young children do. In fact, we now know that children are born “wired” to learn. At birth, the brain possesses more than 100 billion neurons. During the first year of life, it evolves more rapidly than at any other time. By the age of 3 years, 75% of the brain's growth appears; by the age of 5, more than 90% is formed and a foundation is laid for all kinds of competencies—linguistic, conceptual, ethical, social, emotional, and motor. All of these critical dimensions of early development are intertwined in the architecture of the brain, forming a foundation that will shape all future capacities to learn.

New imaging technologies have also demonstrated how affective aspects of children's lives—such as the presence of relevance, interest, enjoyment, good relationships, and feelings of safety and self-efficacy—are critical supporters of learning. The technologies also point out how stress, boredom, confusion, low motivation, and anxiety can interfere with learning. Other research in the social sciences has led to additional understandings about the link between cognitive and social development, and how close and dependable

early relationships promote optimal development. When children do not have such a nurturing environment—or at least one close and dependable relationship—their development can be seriously disrupted.

Even the vocabulary that young children possess is affected by family and life circumstances. A study on language development conducted by researchers Betty Hart and Todd Risley in the 1990s revealed that children growing up in well-resourced families and communities had been exposed to 32 million more words and had significantly larger vocabularies by the time they were 4 years old than those who grew up in less-resourced families and communities.

The research is thus clear that learning is not just a cognitive and physical process but also a social and emotional phenomenon that, in turn, impacts all aspects of growth. Emotions, social relations, and cognition are interwoven. The research is also clear that development does not proceed in a uniform, one-size-fits-all manner. Rather, different children bring different strengths and intelligences to the learning process. They develop at different paces and in different ways. Diversity and variation are the norm.

Quality Early Education and Care: Turning Knowledge Into Action

The educational implications of these understandings are also clear: Children are more successful when they are healthy, physically and emotionally; when they are provided with broad, challenging, and engaging experiences; when they feel connected to the people in their school and broader community; and when schools are safe and trusting places. For young children, this specifically means providing quality cognitive stimulation, rich language environments, and the facilitation of social, emotional, and motor development in the context of good physical care and warm affective relationships. Such quality, caring environments improve social and intellectual competence and the ability to take advantage of subsequent learning opportunities. Some indicators of what this looks like are discussed next.

Attention to the full range of early development in programs that care for and educate young children. High-quality early childhood education pays attention to the full range of factors that impact the health and well-being of not only children but also their families. The knowledge base on young children's emotional, regulatory, and social development is translated into effective strategies for fostering (a) the development of curiosity, self-direction, and persistence in learning situations; (b) the ability to cooperate, demonstrate caring, and resolve conflict with peers; and (c) the capacity to experience the enhanced motivation associated with feeling competent and loved.

High-quality teaching practices and curricula. Teaching practices, curricula, and assessments in high-quality programs are guided by what is known from research about children's thinking and their learning. Special attention is given to approaches that help children from different cultural and linguistic backgrounds, different developmental levels, and different learning styles and strengths. Here are some descriptions of what this looks like:

- Curriculum is based on meaningful and purposeful experiences that utilize the active multimodal nature of young children's learning, such as interdisciplinary studies that include such varied activities as investigations, projects, experiments, and trips.
- Classrooms are provisioned for hands-on learning, with objects that can be manipulated to understand mathematics, natural materials for science investigations, supplies for explorations in the arts, well-stocked libraries, and areas for dramatic play and block-building.
- Schedules for the day include ample opportunities for children to have time for play, that is, the work of early childhood that enables them to construct and consolidate understandings of their experiences and the knowledge and skills to which they have been exposed.
- Literacy-rich environments are in place that involve lots of reading to, with, and by children; lots of talking and listening to and with children;

and lots of opportunities for children to engage with print in natural contexts. Opportunities for children to engage with print can include making signs for the block buildings they create, documenting science experiments, reading recipes for cooking, making charts to review class learning, writing letters, and designing books.

- Explicit attention to skills and knowledge is embedded in active learning contexts rather than instructing through isolated drill. This can include learning letter–sound correspondence through rhymes, games, and chants rather than worksheets; developing a sense of number through everyday activities such as passing out snacks, lining up for recess, talking about number concepts in story books, playing games, and engaging in activities with manipulative materials rather than through rote counting of symbols.

Assessment that informs instruction. Key to carrying out curriculum that is responsive to and supportive of learners’ understandings is using assessment to inform teaching. Quality early childhood programs assess young children through instruments that best reflect information about their progress and use these to inform and guide further teaching.

Multiple forms of evidence collected in the context of natural learning environments offer the most authentic feedback about how and what young children are learning. Many professional associations, such as the National Association for the Education of Young Children, the National Association for Early Childhood Specialists in State Departments of Education, the National Association of School Psychologists, and the National Research Council, support the use of observational assessments while opposing standardized testing for young children as inappropriate and unreliable measures of their learning. Observational assessments can include interview protocols, checklists, and descriptive notes; performance tasks; collections of children’s drawings and writings; as well as photos and/or videos of children at work in the classroom. The information drawn from these instruments can be assessed in

relation to learning continua that describe the progression of children’s skills and knowledge along a trajectory of development. Analysis of these data acknowledge the natural variation of multiple, mutually interdependent domains of growth (i.e., rather than requiring targets that all children must achieve at the exact same time, children’s progress should be noted in relation to “reasonable expectations” of achievement established for children at different ages). Tools like these can be used to aggregate information for accountability purposes. They are also educative for teachers, children, and their families because they offer images of developmental pathways toward the attainment of important skills and knowledge.

Conclusion: Early Education and Care Matter

The research literature on development and learning and on early childhood education and care suggests that the quality of care children receive in their early years is critical to ensuring that they experience a life of personal fulfillment and economic success. There is also consensus that “quality” is signified by a relationship between child and caregiver in which the adult is responsive to the active nature of the child and the full range of the child’s needs—social, emotional, physical, as well as cognitive—that influence development. Laying the foundations to support young children to meet the challenges of 21st-century skills and expectations can best be accomplished by providing them with opportunities that will ignite their curiosities, use their minds well, build their capacities to self-regulate, nurture their intrinsic motivation, and enhance their feelings of self-efficacy.

DEFINITION OF PLAY

See Play, Definition of

DEPLOYMENT AND PARENTING

The first decade of the 21st century saw the United States involved in simultaneous wars in Iraq and Afghanistan. These wars involved the participation of more than 2.2 million service members, with deployments involving both active duty (“regular”) military personnel and a substantial number of National Guard and Reserve service members.

In 2009, approximately 1.98 million children had one or both parents in the military. Thus, a substantial number of children have been affected by the deployment of one parent, and sometimes two parents simultaneously, and by the anxiety and uncertainty associated with having loved ones in harm’s way. A small but growing body of empirical literature has documented children’s adjustment during and following deployment, as well as the influence of deployment on service members’ well-being and their parenting. Although more longitudinal studies are needed to examine how children are most affected, which children are most vulnerable, and through what mechanisms deployment affects children, the current state of the research literature suggests that deployment is a potential risk factor for children’s emotional and behavioral problems.

Moreover, a growing body of research suggests that the impact of deployment on parents (both those who are service members and their non-deployed partners) also extends to children. For example, sequelae of combat such as post-traumatic stress disorder, substance abuse, depression, and traumatic brain injury affect a parent’s capacity to parent effectively. Children, then, may be both directly and indirectly affected by a parent’s deployment. They may be directly affected by the anxiety and worry for the deployed parent and indirectly affected by the difficulties in parenting that may be experienced by the returning service member as she or he reintegrates into family and society. Parenting difficulties may be compounded when a parent is dealing with physical and/or psychological injuries sustained in war. Thus, while the very fact of a separation from a child is

stressful to parent and child alike, the additional stressors associated with exposure to combat may add to the family readjustment and reintegration challenges in the year or more following the return home.

Family stress models suggest that family transitions increase risks for children's maladjustment via the negative impact of these transitions on parents and parenting. Gerald Patterson's social interaction learning model describes how stressed parents become more coercive in their interactions with their children. Children exposed to, and engaging in, coercive interactions (i.e., escalating negative interactions and aversive behaviors that are negatively reinforcing) learn that coercion is a way of life and in turn model these coercive interactions, increasing the potential for behavioral and emotional problems.

Fortunately, a large body of literature has demonstrated that stressed parents can benefit from evidence-based parenting programs. The parent management training–Oregon (PMTO) model, which is empirically derived from Patterson's social interaction learning model, has demonstrated efficacy and effectiveness in improving parenting and child outcomes for a range of populations experiencing family transitions.

After Deployment, Adaptive Parenting Tools (ADAPT) is an adaptation of PMTO for military families and represents the first research-based parent training program for military families with school-age (4- to 13-year-old) children. ADAPT may be delivered as a 14-week multifamily group program, as a self-directed online program, or in an individual telehealth format (online plus a facilitator available via Skype). ADAPT integrates the core components of PMTO: positive involvement with children, teaching through encouragement, family problem solving, effective positive discipline, and monitoring and supervision. In addition, ADAPT provides a strong set of skills in emotion socialization and emotion regulation—helping parents to respond to their own emotions and to teach their children effective tools for learning about and regulating emotions, using mindfulness and emotion coaching strategies.

As of mid-2015, ADAPT was being evaluated in two randomized trials with mostly National Guard and Reserve families. In the first trial, 336 families were randomly assigned to ADAPT or services as usual; in the second trial, for which recruitment began in summer 2015, 360 families were to be assigned to one of the three formats of ADAPT to test the comparative effectiveness of each format. Preliminary data from the first trial suggest that the program is both engaging and effective in strengthening parenting and family relationships: Mothers and fathers participated equally and at high rates, reporting strong satisfaction with the program. Following the end of the program, parents in the ADAPT group reported stronger couple relationships, better observing of emotions, and higher parenting efficacy and self-reported effective discipline than parents in the services-as-usual group. At 1 year post-baseline, families who went through ADAPT reported their children to have fewer adjustment problems, mothers' observed parenting was significantly better, and observed parenting of fathers and mothers was significantly better among those who showed poorer parenting at baseline. Families in this trial were to be followed for 2 years; complete outcome data for the sample are expected by late 2016.

DETERMINANTS OF CHILD DEVELOPMENT

Biological, social, economic, and environmental factors interact with the child, the family, the community, and the broader sociopolitical and historical contexts to determine a child's development. Theoretical frames of reference for understanding how these factors interact include Urie Bronfenbrenner's ecology of human development and sociocultural theories such as the work of Lev Vygotsky. Research has demonstrated relationships among developmental determinants to explain developmental pathways for children.

Theoretical Models of Developmental Determinants

According to Bronfenbrenner's theory of ecological development, human development occurs through increasingly complex reciprocal interactions between the child and the people, objects, and symbols in the immediate external environment. Intraindividual factors include each person's dispositions; their abilities, experiences, knowledge, and skill; and their personal characteristics that invite or discourage reactions and interactions from the social environment. Bronfenbrenner's ecological model consists of a series of structures, beginning with the microsystem, the person's immediate setting, and the mesosystem, the relationships between the settings. These proximal forces that act within the microsystem and mesosystem exert the strongest influence on development; however, they must interact with and on the child on a regular basis over an extended period of time to affect development.

Interactions from the macrosystem, such as the broader cultural values and beliefs that permeate societies in which development occurs, and exosystem, or settings in which the developing child is not directly involved but is affected, influence the proximal forces to further impact developmental trajectories and pathways. The extent to which proximal forces produce development varies with the characteristics of the

developing child, the immediate and more distal environmental contexts in which the processes are taking place, and the particular time periods in which the processes take place.

Processes

Developmental determinants are biological, socio-cultural, and environmental factors that interact across spheres of influence such as parenting, socioeconomic status, and community health and resources. These spheres of influence contribute to trajectories that open pathways along which development proceeds and they continue to affect development over time. Pathways are both individualistic and interdependent, embedded within cultures, and parts of larger sociocultural systems. As determinants change as a result of positive interactions or "investments" and interventions, trajectories onto new pathways may emerge.

At every stage of our lives, factors associated with social advantage or disadvantage determine developmental pathways and outcomes as they accumulate over time to create favorable opportunities or daunting obstacles to development. Interventions early in life can interrupt unfavorable cycles associated with social and economic disparities within the macrosystem, the employment conditions in the exosystem that affect family health and well-being within the mesosystem, and childhood development in the microsystem. Over time the cycle is expressed in the chronosystem, a part of Bronfenbrenner's model referring to the changes in society over time that affect the individual, in terms of the adult's health and well-being.

Determinants of Development

Determinants of child development include the biological endowment of the child as determined by the child's genetic makeup, the culture, and environment in which the child lives. Together, these forces interact to create potentials or pathways along which the child will develop. Social determinants of child development refer to the family's access to income, goods, and services that include health care, education, employment, and

safe homes and neighborhoods. Environmental determinants include the physical, chemical, and biological factors external to people that impact their development. Access to clean air and water and safe and healthy workplaces, homes, and communities determine potential pathways for healthy development.

Biological Determinants

Biologically based determinants of development are laid within the genetic material of each child and are affected by the quality of prenatal care and health of the mother prior to birth to set the parameters for physical, social, emotional, and cognitive development. However, physiological, psychosocial, and environmental influences further affect the child's potential development. For example, physiological development is dependent on securing nutritional foods to support bodily growth and functioning that leads to health. To that end, the infant must be able to communicate and receive nutrition from the mother. As the infant receives nutrition from the mother and the mother responds with appropriate nurturing attention during feeding, this joint participation can lead to healthy attachment that supports brain functioning as well as behavioral adaptation for participation within the family and community.

Healthy attachment to a primary caregiver is a developmental determinant that has been linked to the child's overall physical health and well-being, to cognitive and language development, and to social-emotional development. Affecting healthy attachment is the goodness of fit between the child's temperament and that of the primary caregiver. For the mother to bond with her child, she must sense that her efforts to respond to her child and to elicit positive attention are met with a child's positive attention returned to her. The ways that mother and child contingently initiate and respond to one another support the development of healthy attachment bond between them. As the nurturing relationship is created and sustained, there are increased opportunities for playful physical interactions, social exchanges involving language, and cognitive stimulation. The accompanying

sense of well-being leads to the development of the infant's mental and emotional health, creating a pathway for optimal child development. However, when the child is not responsive to the mother's attempts to soothe or interact or the mother is incapable of positive interactions because of stress, depression, or ill-health, then the formation of the attachment bond is at risk. As a result, infants may become withdrawn or anxious, unable to develop trusting relationships that allow them to venture out beyond the immediate care of the parent to explore environments and develop healthy relationships with others. With such a pathway and without intervention, there are significant risks for physical and mental health outcomes that can extend into adulthood.

Furthermore, environmental factors affect the quality of life in ways that also affect the child's development. Access to clean water, an adequate supply of nutritious food, and protection from environmental toxins are examples of factors that support healthy development. Taken together, the interactions among the child's biological endowments with the physiological, psychosocial, and environmental demands of life can lead to the development of autonomy and social participation.

Social Determinants

Social determinants of child development include parental/family income, education, and employment that, taken together, impact socioeconomic status and affect access to health care, quality early learning programs and schools, and safe housing and neighborhoods. These determinants emerge from the unequal distribution of power, income, goods, and services to differentially affect developmental trajectories, pathways, and cycles. Parental social and economic resources can affect the quality of their relationships with their infants and young children. If parents are to provide for the healthy development of their children, they need access to adequate financial resources to meet the basic needs of food, clothing, and shelter, as well as social networks of support for those facing parenting stress and mental health issues.

Family Resources. Family resources are correlated with children's health and behavioral, emotional, and cognitive outcomes. They include income, time, human capital, psychological capital, and social capital. The impact of globalization has negatively affected family resources in that incomes have been reduced and subsequently, capacity of communities to invest in infrastructures that support and promote child development have been reduced.

Family Income. Factors associated with family socioeconomic status include employment, income, and education. Taken together, these factors affect the family's ability to access resources that support the healthy development of their children. Family income is directly related to the family's ability to acquire shelter, food, clothing, and health care. For families with limited incomes, stressors associated with poverty can exacerbate challenges parents face with rearing children. Poverty stressors negatively affect satisfaction with parenting roles and responsibilities. Parental mental health issues (such as anxiety and depression) and ability to provide healthy food, safe housing, and adequate clothing interact to negatively impact parenting, creating barriers to healthy development.

For families in poverty, developmental outcomes are reflected in limited material resources available in the home to stimulate language and cognitive development and in the limited psychosocial resources available to parents for providing stimulating experiences as a result of stressors associated with trying to provide for basic needs. As a result, children from lower income families tend to lag behind their peers from middle and upper income families in vocabulary development and cognitive skills. The inability of parents living in poverty to provide intellectually stimulating materials (e.g., toys and books) and experiences (e.g., high-quality care and early learning programs) can lead to these parents being less responsive to their children, further affecting cognitive and language development.

Low income is also associated with lower parental education, further affecting their understanding of how to access available resources and

provide the kinds of attention that engages their children in conversations, experiences with books, and community resources that can mediate the adverse effects of poverty. Additional factors associated with poverty and socioeconomic disadvantage include childhood mental health problems, overweight and obesity concerns, and child abuse and neglect.

Further compounding the negative effects of poverty on developmental outcomes is the impact of psychosocial and material circumstances as early as conception that embed themselves in the child's biology through the process of neural sculpting that affects brain development. Families with lower socioeconomic status, maternal education, and family income are also more likely to have poor nutritional status that reduces overall caloric intake, minimizes the specific nutrients necessary for central nervous system functioning, and can result in increased chronic health conditions such as asthma. They are more likely to live in neighborhoods that contain sources of lead, PCBs, and other toxins that impair cognitive functioning. They are more likely to provide home and child care environments that provide less cognitive stimulation, further limiting cognitive development. Access to health care for comprehensive developmental screening to detect early developmental delays and regular check-ups to secure timely immunizations and preventive care is more limited for families with limited economic means.

Although there is considerable variability among children from low-income backgrounds, bidirectional influences, particularly between mother and child, have been found to influence development in these domains. Some parents living in poverty are able to successfully overcome the limitations and barriers they face by actively seeking out resources within their systems of support to alter developmental pathways for their children.

Time. As a result of the global economic downturn, shifts in employment patterns from steady full-time employment to part-time or contract employment and weekend and night shift schedules have affected the earning capacity of families. In addition, these shifts in working schedules can

create increased work-related stress and undermine stability of marriage and family cohesiveness by reducing opportunities for families to spend time together, share in family-related activities, and participate in community social networks. Such nonstandard employment is also associated with poor educational outcomes for children.

Family Composition. Shifts in family composition are associated with impact on family resources. More single-parent families, more women in the workforce, and more grandparents as primary caregivers impact child health and development by interrupting the proximal processes and altering parental resources. Although many single parents build networks to manage child care and extend supportive relationships for themselves and their children, many children experience discontinuity and unpredictability in establishing trusting relationships, particularly with adults. Such relationships are necessary for children to become autonomous and socially competent individuals. Family composition is correlated with outcomes in physical development and health, mental health, academic achievement, and self-regulated behavior.

Parenting Styles. A consistently responsive parenting style is associated with the trajectory for a positive developmental pathway and remains significant in maintaining healthy development. Positive reinforcement, displays of warmth and affection, and the use of authoritative parenting approaches in which parents explain reasons for discipline have been associated with positive academic competence and peer relationships that lead to enhanced child health, well-being in the social-emotional domain, and development of cognitive abilities. Such positive approaches to parenting can mediate the adverse effects of poverty for children; however, the ability of parents to provide positive parenting is made more difficult by factors such as limited incomes, unemployment, and depression. Such chronic stressors are associated with increased incidences of child abuse and neglect, creating additional barriers to healthy development.

Neighborhood and Community Influences. Factors within neighborhoods and communities that determine children's development include exposure to unsafe social and psychological conditions, social organizations with role models and shared values, institutions such as schools and community services, and formally and informally organized peer groups. Influences from the neighborhood and community in terms of cohesion and shared concerns for safety as well as more formal resources available to support families such as community-sponsored activities and opportunities for physical activity on playgrounds can serve to mediate the limiting effects of family income for offering enriching experiences and can provide additional support for families by extending social networks, thereby ameliorating some of the disadvantages associated with poverty.

Access to High-Quality Early Care and Learning Environments. High-quality early childhood programs have been shown to act as investments and effective interventions in determining positive developmental outcomes. Working in concert with families to provide enriching learning experiences that extend the scope provided by parents, early childhood programs that target the acquisition of social and emotional skills as well as stimulating cognitive and language development maintain the positive trajectories of children on a pathway of healthy development.

For children whose families have limited economic and social resources, high-quality early childhood programs like the Perry Preschool project, the Chicago Child-Parent Center program, and the Carolina Abecedarian Project have been found to be effective interventions that address the short-term outcomes in all developmental domains and over time, to maintain a positive pathway in terms of educational completion, successful entry into the workforce, and less dependence on social welfare programs.

Environmental Determinants

Environmental determinants of development affecting the individual child's trajectory include

the physical, chemical, and biological factors external to the child that can impact development. Environmental toxins that include air and water pollution, lead and asbestos, and neighborhood crime all affect the level of health and safety within the home, community, and workplace to negatively impact living and working conditions. Families and children from poverty are the most vulnerable to these environmental factors. Set within the context of the macrosystem, the policies that are put in place to manage pollutants and adopt cleaner, more sustainable energy technologies and water sources address the negative impact of pollution and environmental toxins while simultaneously promoting healthy development. Within the exosystem, the implementation of policies and practices that eliminate environmental toxins present in low-income housing (e.g., lead, asbestos) improves the quality of life.

Investments and Interventions

Although the determinants, present at birth, set trajectories along particular pathways of development, many can be modified in ways that shift the trajectory to paths that become increasingly positive or negative. From the distal macrosystem and exosystem to the proximal mesosystem and microsystem, investments and interventions provide the necessary support for proximal systems to act and react to offer the most positive interactions that establish pathways for healthy development. Ongoing supports can build a cycle of positive development over time. However, emergence of chronic disease, serious physical injury, and loss of family income are examples of determinants that can shift pathways in negative directions.

One pathway that fosters children's development includes parental education and employment that provides the financial and psychosocial resources to access adequate food, housing, and medical care. As a result, parents are able to invest resources in stimulating materials and experiences, high-quality early childhood care and education programs, and safe neighborhoods that further support healthy development. However, many

lower income families have limited resources for investment. Economic hardships are associated with limited access to preventive medical care, nutritional foods, and safe, affordable housing. Such hardship also creates stress that is associated with poor mental health, interparental conflict and family disruption, poor parenting skills, and child abuse and neglect. Interventions to address these developmental determinants can serve to shift the trajectory from risk to promise. Such interventions may be provided through publicly or privately funded programs and may occur as individual, focused interventions (e.g., employment programs, food stamps, housing vouchers) or more comprehensive measures that include health, mental health, social services, and education/job training components (e.g., Head Start).

DEVELOPMENT OF PREJUDICE

The existence of prejudice among adults is well-documented in academic research but is also evident to the casual observer in everyday life and in conflicts around the world. But do *children* experience and express prejudice? How does this develop with age? What is driving its development? And what does this mean for tackling prejudice in the early years?

In the past 80 years researchers have been intrigued by, and compelled to study, the expression and development of prejudice in children. Research in this area has tended to focus on ethnic and racial prejudice and also on the views of majority group children. This entry reflects this bias in the research but also describes the (limited) research on prejudice in young members of minority groups.

Prejudice in Children

Prejudice can be defined as attitudes, feelings, or actions toward members of a group that imply negativity or hostility toward that group. This could include biased attitudes, hostile feelings, and discriminatory behavior toward a group in general or toward individual members of that group. Prejudice can be based on group memberships such as race, ethnicity, language, disability, sexual orientation, nationality, or even “minimal groups” (new and arbitrary groups created in experiments) and teams. Some research has uncovered overt, hostile prejudice in children, but researchers more often focus on bias. This is a preference for or favoring members of one’s own group compared with another group. Although this may appear relatively benign, researchers regard such behavior and attitudes as problematic, because members of other groups will always lose out relative to children’s fellow group members. This maintains segregation, stereotypes, and negative relations between social groups.

Landmark research in the development of prejudice in children was conducted by Eugene Horowitz and by Kenneth Clark and Mamie Phipps Clark in the 1930s and 1940s. Their compelling research findings have inspired 70 years of subsequent study, and the methodology has provided a blueprint for research in this area. In this early research, conducted in the United States, children were presented with either dolls representing Black and White racial groups or photographs of White and Black children. Typically children were then asked which doll or photo looked most like them. They were also asked questions designed to tap into their preference for, and attitude toward, their own (or the other) racial group. For example, children were asked which doll they would like to play with and which one they liked the best. This early research showed that from a very young age (preschool), White children identified with the White stimuli. They also showed a clear own race bias as they were more likely to select the White stimuli as the one they liked best and wanted to play with. Black children, on the other hand, and in particular very

young children (3 years old), were more likely to self-identify with and prefer the *White* stimuli.

Numerous subsequent studies have replicated these findings with majority group children in different countries, different ethnic groups, and different historical and sociopolitical contexts. Research has shown that prejudice and bias can manifest themselves in numerous ways in childhood, including resource allocation of stickers or sweets, choice of playmate, positive and negative evaluations, social distance, interpretation of ambiguous situations, and desire for future interaction. In addition to race, ethnicity, and gender, there is also evidence of prejudice and biased attitudes and behaviors based on body type and disability.

Importantly, whereas this finding is relatively consistent among children belonging to the majority social status group, findings among children belonging to minority status groups are more varied, but it appears children in these groups are more ambivalent toward their group and do not always show clear bias toward their own group members, particularly in preschool and in the early school years.

Researchers have also used artificially created groups to try and learn more about the development of prejudice in children. These studies typically randomly assign children to arbitrary groups or teams and physically demark group membership through colored T-shirts, for instance. Research has shown that even these arbitrary and superficial group memberships lead to bias. For instance, Rebecca Bigler and colleagues showed that when children are placed in groups based on T-shirt color for just 6 weeks, children evaluated their own color group more positively than the other group and preferred playing with members of their own color group. Similar results have been demonstrated in other contexts, such as team games or drawing competitions. These groups have no historical context, are short-lived, and are superficial. Yet children use them to make decisions about who they want to play with and how they evaluate other children. Furthermore, threat, competition, and strength of attachment to the group all heighten the effect of group membership on children's evaluations of their own and other groups.

Developmental Trajectory of Prejudice in Early Years

The majority of research has shown that among majority group children, racial bias first appears at an early age (as young as 3 years). This preference for one's own racial group rises, along with negative views of other racial groups, until approximately 7 years of age, when it peaks, before it gradually declines. This pattern of findings has been demonstrated in many studies in the United States and in other countries. These studies have tended to focus on racial prejudice, because of the context of the research. Other forms of prejudice, toward other nationalities for instance, seem to show a different developmental pattern and may appear later, whereas gender bias can appear very early in children from 2 years of age and continue beyond 7 years of age. Less is known about developmental trends of bias among minority status children, and research to date suggests variable patterns of development, where very young children may favor the high-status racial group and older children may show more ambivalence toward their own group.

Drivers of Prejudice Development in Children

Intuitively, many people would argue prejudice in children is a result of socialization by sources such as parents, peers, and the media. From a psychological perspective, the socialization of such attitudes could be direct, through modeling of behaviors, imitation of them, and reinforcement, or more indirect, where children merely observe typical behaviors and attitudes (like observing little interaction between one's own group and others) and integrate these in their own repertoire.

The lack of representation of minority groups and the presence of cultural stereotypes in children's media is well-documented. However, we know less about the link between this and children's attitudes. Research suggests that carefully designed children's TV programs and story books depicting cross-group friendship can have an impact on children's attitudes, but the long-term

effect is unknown, and the effect on hostile and extreme prejudice may be more limited.

The other main source of influence, particularly in early years, is parents. Although findings are mixed, a recent review concluded that children's attitudes are linked with those of their parents. However, there are a number of important caveats to keep in mind when considering this finding: It is possible that children's attitudes and parents' attitudes are both products of the same social context (e.g., they both live in a highly racially segregated society). That being said, recent research has attempted to examine more closely the process by which parental socialization of racial attitudes occurs. Luigi Castelli and colleagues' research has linked (ethnic majority White) parents' *unconscious* racial attitudes and their *nonverbal behavior* in interactions with racial out-group members (e.g., eye gaze, body language) with children's racial attitudes. In their research, it was found that young children use nonverbal cues by adults in interracial interactions to determine the extent to which the adults enjoy that interaction, and this then influences children's attitude toward a new, "Black" person they are asked to evaluate. Other research has shown that (majority White) children's racial attitudes are linked not with parents' attitudes but with the number of interracial friendships held by parents. In summary, the findings on the link between media, parents, and children's racial attitudes are mixed. However, it seems that children may pick up on cues about how typical and positive interracial interactions are and use this to inform future evaluations of members of other racial groups.

An alternative approach to the development of prejudice in children links racial attitudes to children's cognitive, social, and affective development. The most prominent of these theories is Frances Aboud's social cognitive developmental theory. This perspective suggests that prejudice in children is a result of their cognitive mind-set, which provides a lens through which children organize, process, and assimilate information. According to this approach, the increase in prejudice observed in children from preschool to 7 years of age can be explained by achievement of

well-established cognitive abilities (e.g., conservation, constancy), knowledge of stereotypes, and a change in preoccupation with the self (in young children) to groups (from 5 years up) as children need to use groups to make sense of their social world. These changes in cognitive ability, preoccupation with physically salient groups, and increased awareness of stereotypes explains the observed peak in prejudice at the age of around 7 years. This is followed by a decline in prejudice as children focus again on the individual, begin to understand variability within groups, and stereotypes are broken down. There is some support for these approaches in general: They are thought to be valuable, as they allow the child a more active role in the development of their attitudes. Also, some research has linked perspective taking, conservation, reconciliation of attitudes, constancy (the understanding that social groups are constant over time), and ability to group people together in multiple ways to prejudice and bias in children. However, findings are mixed and this approach has been criticized for ignoring the important role of parents, peers, and social context in shaping children's attitudes.

More recent research on prejudice development in children has highlighted the importance of the strength of children's identification with the social identity in question (e.g., ethnic identity) and (peer) social norms for the expression of prejudice and bias.

Practical Applications

Overtly negative attitudes and discriminatory behavior toward members of other groups are rare in children, as they are in adults. However, bias toward and preference for one's own group is more common; it is also considered to be problematic because preference may lead to behaviors that derogate the out-group and lead to segregation. Research suggests that bias appears very early in ethnic majority children's lives (from 3 years), and bias and prejudice increase to a peak around 7 years of age where they trail off. For ethnic minority children the findings are more mixed, and for intergroup contexts other than

race, such as nationality, findings appear to follow a different developmental trajectory.

So far we have considered a number of drivers of the development of prejudice in children: social context, cognitive abilities, and social identity. These approaches have implications for practical interventions for use with young children. First, it appears that adults' nonverbal behavior, and observing comfortable interactions between group members, is important for propagating positive ideas about intergroup relations and creating positive evaluations of out-group members. Second, the social cognitive approach suggests that children's cognitive abilities (e.g., reconciliation, multiple classification) may limit or shape the impact of attempts to change their attitudes. For instance, children's preoccupation with groups and their inability to recognize variability within group may limit their ability to process information conveyed in educational materials (such as multicultural stories) or information from adults that aims to reduce prejudice and tackle stereotypes. The social cognitive approach advocates the use of cognitive training alongside such educational techniques. Finally, the social identity approach emphasizes the importance of tackling prejudice by changing social norms and expectations.

Conclusion

Prejudice is evident among young children, and although this is surprising and concerning, it is important to remember that for the most part, children express bias—a preference for their own group—and the negative hostile behavior we sometimes observe in adults is rarely found in children. It is important to also remember that young children's bias and prejudiced attitudes and behavior may be a result of their (naturally developing) preoccupation with physically salient groups: "What group do I belong to? What group are they? I like my group best." However, children learn about the status of groups, stereotypes, and typical intergroup relations (how the members of the groups get along) through observing parents and other adults in their world. Crucially, research shows that children can and do respond to educational

interventions to change their attitudes, particularly if they are tailored to suit their cognitive ability.

DEVELOPMENTAL ASSESSMENT

Developmental assessment is a process designed to deepen an adult's understanding of a child's competencies, capabilities, and progress in multiple domains of development—physical, intellectual, language, emotional, and social. It is usually conducted when a physician, parent, or teacher notices that a child is experiencing a developmental problem in one of these areas. This entry provides information about the purposes and qualities of developmental assessments along with information about some of the more common assessments in use in early childhood education today.

A developmental assessment typically includes a wide variety of measurement methods such as observations and outcomes of the child performing various tasks; observations of a child in natural/authentic settings (such as homes and classrooms) as they interact with others or play on their own; questionnaires completed by parents, caregivers, and teachers; medical/vision examinations,

medical history, and reports from other professionals such as audiologists, language specialists, child psychologists or psychiatrists, and physical and occupational therapists. Often a team approach involving many people is used in a developmental assessment. A developmental assessment appraises development of the child along a continuum of developmental milestones and thus does not result in a traditional “score.”

Those performing a developmental assessment should consider the value of the following chain of events.

1. First, build a relationship with the parent or caregiver and discuss issues and concerns of the child *and* of the family.
2. Obtain as much developmental history as possible as well as information on current family experiences and dynamics.
3. Observe the child in the context of spontaneous play and daily routines with parents and/or familiar caregivers.
4. Conduct specific assessments of the child in developmental area(s) of concern.
5. Observe interactions between the child and the evaluator or clinician.
6. Keep a developmental model as a framework to understand and integrate all of the data, thus creating a picture of the whole child.
7. Convey evaluation findings in the context of relationships within the family.

In a more narrow definition, a developmental assessment is any assessment whose focus is on development in the various domains rather than academic knowledge, skills, or abilities. Various developmental assessments can be purchased from companies and institutions. A few of the well-known and popular ones include Ages and Stages Questionnaires (ASQ-3), Denver Developmental Screening Test (DDST), Early Screening Inventory-Revised (ESI-R), Gesell Developmental Observation-Revised (GDO-R), and Hawaii Early Learning Profile (HELP). All of these assessments

have the advantage of availability to collect data longitudinally to monitor children’s growth over time.

The ASQ is a highly reliable assessment used to screen children, from birth through 5½ years of age, for disabilities. The questionnaire format is completed by parents in about 10 to 15 minutes and scored by professionals in 2 to 3 minutes. As parents complete the form, they are able to gain understanding of both typical developmental expectations and their own child’s strengths and areas of concern.

The DDST was created at the University of Colorado Medical Center in Denver and is primarily used to examine developmental progress in children from birth through 6 years of age. As a screening instrument that takes a relatively short time to administer, it is commonly selected for use in early education programs and pediatric offices. When concerns about a child’s development arise, based on results from the use of this instrument, additional assessments are often scheduled.

The ESI-R is a screening instrument used to identify preschool- and kindergarten-age children who may need special education services. The screening is individually administered and takes about 15 to 20 minutes. Results of the screening are put in terms of one of three statuses: refer, rescreen, or OK.

The GDO-R is an observational assessment that evaluates cognitive, motor, language, and social-emotional development in children between the ages of 2½ and 9 years. Providing information about strengths and areas for additional support to both parents and teachers, the results are particularly useful in planning for differentiated instruction.

HELP is a family-centered curriculum-based assessment for infants and toddlers (birth to 3 years) and their families. HELP Strands 0–3 Plus measures the skills of toddlers, 36 to 48 months of age. These measures evaluate children’s development in cognitive, language, gross motor, fine motor, social-emotional, and self-help skills.

An inherent benefit of a developmental assessment is found in its understandable scope of developmental milestones that informs and advises

parents and teachers as to what is an appropriate expectation for each age. Quality developmental assessments provide a range of time for each milestone to emerge, unlike checklists that simply want a yes or no answer for each milestone by month or year of age.

DEVELOPMENTAL DISABILITIES

Developmental disabilities are a complex, complicated cluster of symptoms and conditions. They are lifelong and chronic. This entry begins with a definition of the condition followed by causation and specific diagnosis. The entry ends with a discussion of the implications of this diagnosis for

early childhood education and particular considerations for early childhood educators.

The term *developmental disabilities* is an umbrella term used to describe a diverse set of disabilities in broad areas resulting from impairments in physical ability, learning, language, or behavior. These conditions often occur prenatally or at a young age but may occur anytime in development as a result of injury, infection, or other factors occurring up to 22 years of age. The key aspects shared by these very different conditions are that they are chronic, are usually lifelong, and typically have an impact on the person's day-to-day functioning.

In his 2008 book, Pasquale Accardo described three general ways developmental disabilities are recognized as different from the typical pattern of expected development in early childhood. First, a child may attain a skill more slowly than expected—the child with delays shows the skills of a younger child. The second difference can occur when a child deviates from the expected sequence of development. A child deviating from the expected path shows behavior not typical of a child at any age or completely fails to acquire an expected skill. The third difference is a combination of the previous two: A child may be delayed, or slow to attain skills in a particular area of development, but may show a much more pronounced or marked delay in other areas. Or, the child may deviate by showing an atypical behavior in another area of development. This third uneven acquisition of developmental skills is described as dissociation.

Causes and Diagnosis

The list of causes attributed to most developmental disabilities is also broad. According to the Centers for Disease Control and Prevention, most developmental disabilities are thought to be caused by a mix of factors, including genetics, prenatal health of the mother, parental health behaviors such as smoking and drinking, complications of birth, premature birth, maternal infections during pregnancy, or post-birth injury or infection. Unlike most other clinical and medical diagnoses, development disability does not have one specific

identifiable cause or outcome. Instead, conditions are generally described by symptoms rather than known causes.

In the 2013 edition of his textbook on medical aspects of disability, Mark Batshaw categorizes developmental disabilities by three levels of significance. Conditions in the first level occur at higher rates and are often less severe. The first level is for specific impairments and very broad behaviors such as inattention, spasticity, and underachievement. The second level is for categorical diagnoses such as attention deficit hyperactivity disorder (ADHD), cerebral palsy, autism, or specific learning disability. The third level is the narrowest and the least frequent. Conditions in the third level are classified by etiology. Down syndrome and fragile X syndrome both fall in level 3.

Level 1 conditions have broad symptoms and characteristics but are not identified by a clear, specific condition. The descriptions in level 1 are more often a way of clarifying function and level of severity. The descriptors in level 1 are vague—inattention or spastic movement is clear enough to describe a behavior, but it is not diagnostic. A more common, functional use of these descriptors is in educational and therapeutic settings. The frequency or intensity of the symptom and behaviors may lead to the diagnosis of a more specific level 2 or 3 condition.

The second categorical or diagnostic level identifies patterns of behavior associated with specific disorders or symptoms that indicate a particular condition such as ADHD or intellectual disability. In 1992, the World Health Organization (WHO) presented another way of categorizing level 2 disorders, in a document titled “The International Classification of Functioning, Disability, and Health” (ICF). The ICF looks at human function. Function describes daily life activities rather than the limitations.

The ICF provides a unified language that captures *how* people with a health condition function in their daily life, rather than focusing only on the diagnosis or the presence or absence of disease. In the ICF, a function is defined as the use of any part of the body in an activity, movement, or participation in life activities. Disability is the limitation.

Environmental and personal factors are considered in each area. The ICF discussion centers on the individual and his or her activities and environments, not just on his or her limits. In recent years there has been a tendency to blend the static categories of disability with the dynamic ICF functions of the person in the context of his or her disability.

Level 3 of the framework laid out by Batshaw is the narrowest level—the etiologies level. The conditions at this level have clearly recognizable characteristics associated with their label. Conditions such as Down syndrome fall in this category. It is the narrowest level because the variability and the incidence of conditions are lower than for the other levels. Level 3 conditions are included here because the etiology of the condition is specific.

The following categories, taken from the Centers for Disease Control and Prevention website, are broad examples of the types of conditions teachers may encounter in the classroom. This is not intended to be an exhaustive list.

Attention deficit hyperactivity disorder is a very common neurodevelopmental disorder that is usually first diagnosed in early childhood. The symptoms include difficulty paying attention and impulsive behavior.

Autism spectrum disorder (ASD) is a developmental delay identified in early childhood but persisting throughout the life span. Individuals with ASD often have challenges with social interactions, communication, and behavior. Repetitive behavior and difficulty with transition from one activity to another are two common symptoms.

Cerebral palsy affects individuals in very different ways. It is a group of conditions that affect a person's posture and movement. Literally, *cerebral* means brain and *palsy* means weakness of muscles. Symptoms range from mild to severe and the impact on daily living is one way the level of severity is measured.

Hearing loss occurs when there is a problem in any part of the ear—outer, middle, or inner. Hearing

loss ranges from mild to moderate in either or both ears. Hearing loss may affect a child's ability to develop language skills, spoken words, and social skills. Hearing loss may occur anytime from birth onward.

Intellectual disability is a condition closely aligned to the term *developmental disability*; in some publications the two terms are interchangeable. Intellectual disability, however, refers to the limitation a person may experience in the level of daily function as a result of cognitive impairment. Delays in development are noted at an early age for children who have intellectual disability. The condition, however, can occur before birth as a result of infection, or shortly after birth as a result of birth defects. Other causes, such as a traumatic brain injury or infection, occur later in the child's life.

Learning disability means a disorder in one or more of the basic processes involved in understanding or using language, spoken or written, that may manifest itself in the imperfect ability to listen, think, speak, read, write, spell, or to do mathematical calculations. It includes conditions such as perceptual disabilities, brain injury, minimal brain dysfunction, dyslexia, and developmental aphasia.

Vision impairment can be due to damage to the eye or a problem with or damage to the brain. The impairment may occur in one or both eyes. The degree of vision loss is variable and can be different in each eye.

Developmental Disabilities for Early Childhood Educators

What do all the development disability conditions mean to an early childhood educator? Whereas many of the conditions described may occur in early childhood, the diagnosis of others, especially the less specific, higher incidence conditions, sometimes takes longer. When a developmental concern is established for a younger child, the emphasis of the concern is not on the chronicity or lifelong nature of a disability; instead, the focus is on the individual child's strengths and weakness.

In the United States, pursuant to the Individuals with Disabilities Education Act (IDEA), children are eligible for early intervention services with an identification of a developmental delay. Each state has specific criteria for both the identification of developmental delay and eligibility for services that include educational and therapy intervention. The behavior or skills in each developmental area are evaluated by observing a young child's achievement of milestones in comparison to a normative sample of children the same age.

Milestones are behaviors and skills that can be repeated by children at generally the same time and in the same way so that an observer can reliably note the presence or absence of the behavior. Milestones are a way of marking development. Batshaw noted in his 2013 text that developmental delay is most often described as the number of months or years a child is behind in the development of a skill or milestone. Milestones tend to reflect important functional skills that are critical to development. In evaluation of child behavior, it is important to focus on the function of behavior the milestone represents, not the specific milestone. A young child's development, while following the sequence set out by the milestones, still has great age variability. A delay in any area is a caution, and a delay of 25% (1 standard deviation) or more is considered a developmental delay.

The following developmental areas are set by the IDEA to determine eligibility for services: physical development, communication development, cognitive development, social or emotional development, and adaptive development.

Physical. Development characterized by behaviors and skills in the motor area of development. The motor area consists of gross and fine motor skills. Gross motor skills, or large muscle movement, include rolling, sitting, creeping, crawling, pulling to stand, standing, transitioning in and out of sitting, cruising along a surface, walking, skipping, running, and climbing stairs. The small muscle movements are viewed as fine motor skills, such as pincer grasp, reaching, swatting, clapping, scribbling, writing, and many self-feeding skills (e.g., holding a cup or spoon).

Communication. Development characterized by the expression or speaking of language and the understanding or reception of language. Children with a delay in listening (understanding) and speaking skills are labeled as language-impaired. Learning to talk is one of the most apparent milestones achieved in early childhood.

Cognitive. Development of mental reasoning, cause and effect, memory, problem solving, and intellectual processes develop in a sequential order that can be observed and anticipated in typical development. Object permanence demonstrated in peek-a-boo, memory of the alphabet, and rote counting are examples of cognitive or thinking skills developed in early childhood.

Social or Emotional. The social awareness and general sociability of a young child is observed and evaluated along with the child's emotional self-regulation and reaction to the environment. What a child experiences as an infant influences behavior, both positively and negatively, and is evident in the development of social and emotional skills. A young child builds trust in the first two years that is a foundation for relationships and social interactions with others. Other skills developed during the early childhood years include social interactions, self-regulation, friendship skills, turn taking, and sharing.

Adaptive. In the early childhood years, the domains of adaptive behavior are generally the self-help skills of feeding, dressing, and toileting.

DEVELOPMENTAL SCREENING INSTRUMENTS

Developmental screening instruments (DSIs) refer to tools used in the process of identification of a disability or delay. Screening instruments are meant to provide a snapshot of early child development. They are used to determine if there is a need for further, more comprehensive evaluation. Results from DSIs are used to make referrals for diagnostic evaluation(s), track child development, and conduct universal screening efforts.

This entry provides information about DSIs used for early detection of developmental problems in young children. DSIs contain items meant to differentiate typical from atypical performance in various areas of development that may include, but are not limited to, the following domains: adaptive, cognitive, communication, fine motor, gross motor, and social and emotional.

Overview

A framework for the use of DSIs starts with a *concern*. Someone familiar with the child has raised a concern about his or her development.

That concern may lead to a *referral* being made for a developmental screening. A familiar caregiver (e.g., parent, grandparent) or professional (e.g., teacher, pediatrician, social worker) completes the DSI.

If the DSI indicates the child performed in the typical range, then he or she may not need further screening. The child may be entered into a tracking system (also called developmental surveillance) in which future screening instruments will be given at a later date to track the child's development.

However, if the outcome from the DSI indicates the child performed differently from what is expected for his or her chronological age, then referral to the appropriate service provider(s) will be made for a diagnostic evaluation.

DSIs are not meant to be used to (a) diagnose a disability, (b) determine eligibility for early intervention or early childhood special education, (c) write treatment or education plans, or (d) monitor developmental progress. Screening instruments usually take less than a half hour to administer and have a small number of assessment items when compared to more comprehensive developmental evaluations. For this reason, results from a DSI can only show a narrow and incomplete picture of what a child can and cannot do. Therefore, a big question that a DSI can help to answer is, "Does this child need further assessment to determine the presence of a delay or disability?"

Cross-sector collaboration is needed when using DSIs. Education, social service, and health care providers can all conduct screening. In education, young children are screened by educators as outlined in the Individuals with Disabilities Education Improvement Act of 2004 (IDEA). Eligible young children and their families may receive early intervention (for infants and toddlers under IDEA Part C) or early childhood special education (for preschoolers under IDEA Part B, Section 619). IDEA mandates states to set up a Child Find system in which DSIs are used to actively identify young children with delays or disabilities.

In the social service sector, young children are screened by social service providers. The Child Abuse Prevention and Treatment Act promotes developmental screening for children who have

been referred for abuse and/or neglect. The American Academy of Pediatrics recommends developmental screening for young children by health care providers and pediatricians.

Research

DSIs are commercially available from publishers. Some DSIs have limited evidence that support their use, whereas others are supported by evidence from several research studies. The user's guide or manual that accompanies a DSI may describe the research studies associated with the tool. Often the DSI is supplemented with a manual that describes the standardization sample, field testing, and other research done during the development phase of the instrument, especially if it is a first edition or newer instrument. A literature review on DSIs can indicate evidence for the validity, reliability, and/or utility of the tool. To have confidence in the effectiveness of the DSIs being used, it is useful to incorporate the use of DSIs that have an evidence base.

Tips in Selecting DSIs

Several considerations need to be made when selecting an appropriate DSI. First, look for screening instruments that involve the child's parent(s). Several instruments have ways to elicit information from the child's family and familiar caregivers. Some use interviews, checklists, questionnaires, and other methods for parental input.

Second, the costs need to be considered. There is a wide range of publisher charges for instruments. Some instruments offer kits and special materials. An agency might look for instruments that allow it to reproduce and make copies of the assessment protocols rather than having to buy a new one for each use.

Third, the characteristics of the child being screened should be represented in the standardization sample when norms were being developed. Screening instruments are norm-referenced assessments. When a child is screened, his or her results are compared to the other children in the normative sample, typically based on chronological age

(e.g., a 48-month-old child is compared to peers of the same age). To apply this tip, consider a child who may have characteristics related to autism spectrum disorder (ASD); in this case, it would be critical to use a DSI that was field-tested on other children with ASD characteristics. Likewise, for a child who is suspected of having motor delay, the evaluator should select a tool that incorporated children with orthopedic impairments or delays in the standardization sample.

Fourth, ensure there is a fit between the existing services and personnel conducting developmental screening. Professional development and technical assistance will need to be considered. It is also important that the resources are streamlined so there is no duplication of efforts. Personnel need to be aware of where, when, and how to send referrals based on screening outcomes, as well as how to follow up on referrals.

A final tip is to select instruments that offer flexible methods for screening young children. Some tools can be administered online, via mail, at a kiosk in the pediatrician's office, at intake, over the phone, in a face-to-face interview, at a screening fair, and more. DSIs that provide flexibility can be beneficial to children, families, and practitioners.

DEVELOPMENTALLY APPROPRIATE PRACTICE

Developmentally appropriate practice (DAP) refers to ways of teaching and caring for young children from birth through age 8 that effectively promote children's development and learning in important domains—physical, social, emotional, language, and cognitive development and approaches to learning—by helping children reach challenging but achievable goals. Dimensions of DAP emerged from and continue to be revised according to two main sources: (a) research on children's learning and development outcomes, and (b) practitioners' experiences in working with young children.

Professionals in the field of early childhood care and education first articulated dimensions of DAP through publications of the National Association for the Education of Young Children (NAEYC) in the 1980s, which were written to help teachers create environments that conformed to how young children best develop and learn. The term *environments* encompasses physical, emotional, instructional, and relational aspects. (In this entry, the term *teachers* refers to anyone providing direct care to infants, toddlers, or young children.) As research and practice have evolved over the past few decades, NAEYC and other researchers and stakeholders have tried to keep pace by revising and expanding materials to explain how to define and implement DAP.

There are several common misconceptions about DAP. First, DAP is not a curriculum, as it is sometimes referred to; rather, it is a collection of considerations about what is appropriate and is designed to help teachers plan and implement

curricula effectively. DAP guidelines help educators select curricula that are effective and beneficial to children. Although DAP is usually referred to in the singular, it is better thought of in the plural, as “developmentally appropriate *practices*,” as it encompasses a wide range of approaches that are dependent on individual children and contexts. What is appropriate for one child may not be appropriate for another, just as good coaching for one athlete looks different than good coaching for another athlete, depending on the individual and the context even though basic principles (e.g., practice, good nutrition) remain constant. However, this entry refers to DAP in the singular because that is how the term is generally used in common practice.

Lastly, DAP has often been closely identified or equated with play-based learning, but this idea greatly oversimplifies and distorts what is meant by DAP. Play—child-initiated, free-choice activity—is essential to DAP but is only one element of it and is only effective in balance with other elements, including direct instruction. In short, DAP is a set of principles and practices that guide educators in caring for and educating young children for their optimal development.

This entry aims to explain what DAP is by first providing a definition and underlying principles, followed by an explanation of how the term emerged in the education lexicon and in practice. A discussion of DAP and research follows. There is then a brief discussion of DAP in the international context. The closing section considers current trends and policies that could impact implementation of DAP in the United States.

Definition of Developmentally Appropriate Practice

DAP describes a set of understandings about what constitutes good practice in caring for and educating children from birth through age 8. One of the central aspects of DAP is that teachers meet a child where she or he is—developmentally, experientially, culturally, individually—and from this starting point take action to enable the child to progress. Thus, best practice begins with teachers’

awareness of individual children’s knowledge, abilities, characteristics, and interests, which is achieved through warm, reciprocal relationships with each child. Teachers use this awareness to make decisions and strategies to help each child meet challenging but achievable goals through learning experiences that are engaging and meaningful to the child.

Teachers make decisions about what is developmentally appropriate based on three core considerations: (1) their general knowledge of child development—knowing what children are generally capable of and how they learn within a given age range; (2) their knowledge of individual children and their unique interests, abilities, and personality; and (3) their awareness of the cultural context and family life in which children live. Professional preparation in early childhood development and education is therefore considered a necessary prerequisite to competent performance as an early childhood educator.

There are five aspects of teachers’ roles within a system of DAP, according to NAEYC. Teachers (1) create a caring community of learners, (2) teach in ways that enhance children’s development and learning, (3) intentionally plan curriculum to achieve important goals, (4) use appropriate assessment strategies to guide children’s development and learning, and (5) establish reciprocal relationships with families. Regardless of children’s ages, developmental status, family background, or cultural context, these five aspects of teaching are considered fundamental to DAP.

As described in the 1997 and 2009 position statements on DAP, DAP stems from 12 core research-based principles about children’s learning and development:

1. All areas of development and learning are important.
2. Learning and development follow sequences.
3. Development and learning proceed at varying rates.
4. Development and learning result from an interaction of maturation and experience.

5. Early experiences have profound effects on development and learning.
6. Development proceeds toward greater complexity, self-regulation, and symbolic or representational capacities.
7. Children develop best when they have secure relationships.
8. Development and learning occur in and are influenced by multiple social and cultural contexts.
9. Children learn in a variety of ways.
10. Play is an important vehicle for developing self-regulation and promoting language, cognition, and social competence.
11. Development and learning advance when children are challenged.
12. Children's experiences shape their motivation and approaches to learning.

DAP has had a strong influence on the early learning standards in many states and on curriculum resources that have been developed in recent decades, and proponents of DAP advocate for policy makers, aid organizations, and foundations to consider its principles to guide policy and funding decisions. However, the fundamental goal of DAP is for teachers to use the principles of DAP to make teaching decisions to best promote individual children's learning and development.

How Developmentally Appropriate Practice Emerged

Originally used by developmental psychologists at the beginning of the 20th century, the term *developmentally appropriate* describes age-related and individual variation in human development. The term was sometimes used by psychologists and others to describe experiences and materials that suited children's particular point in development, and in the early days of Head Start educators agreed that programs needed to be implemented in "developmentally appropriate ways." The term

came into wide use in the field of early childhood education when NAEYC published a position statement in 1986, defining and describing DAP in relation to teaching children in early care and education programs.

The First Position Statement: Combating Push-Down Curricula

Societal changes intensifying in the 1980s, including greater numbers of families seeking child care for children at younger ages, converged with an increase in the use of curricula and practices inappropriately pushed down from older to younger children. For the most part, educators did not intentionally push down practices they knew to be inappropriate; rather, not knowing better, they overgeneralized their beliefs and accepted elementary teaching practices for young children. These methods and curricula were typically not well suited to young children: They required them to sit still for too long, follow teacher directions too often, do things in whole groups too long, or complete overly difficult worksheets. Little time was protected for active engagement, including play, exploration, and problem solving. Some teachers noticed children struggling, failing, or being judged not ready for the next level. Educators observed these practices to be either boring or frustrating and discouraging to young children, leading to a consensus that the field needed to protect young children from learning experiences designed for older children that were ill-suited for young children's ways of learning.

In response to these "push-down" practices—as well as a need to clarify DAP for programs seeking NAEYC accreditation and to make interpretation of standards more consistent—NAEYC published its 1986 position statement. It summarized the field's best thinking at the time, served as a defense of valued practices, and was used as an advocacy tool to improve programs. NAEYC expanded the position statement into a book in 1987, edited by Sue Bredekamp. These were pivotal publications for the field because NAEYC, representing early childhood teachers,

administrators, advocates, and policy makers, articulated its position on how to best educate young children in ways that suited their developmental characteristics and avoided the push-down approach. In the 1986 publication on DAP, NAEYC provided extensive examples of appropriate and inappropriate practices in order to guide teachers to make decisions that would best support young children's learning, according to both developmental levels and individual abilities, interests, needs, and learning goals.

Consensus and Criticism

NAEYC's position on DAP was widely embraced by the early childhood field, but not universally. For example, in the Commonwealth of Virginia, educators were asked not to use the term *developmentally appropriate practice* in state professional development programs. In general, critics challenged what they perceived as an overly narrow reliance on traditional theories of child development and worried that the DAP statement promulgated a hands-off, laissez-faire image of teaching practices in which the teacher merely set up a good environment and then stood back to watch. Others argued that the statement on DAP failed to note the importance of cultural differences in determining what practices are and are not appropriate. Critics also pointed out that DAP, as it was then defined, paid insufficient attention to special needs and other individual differences.

Other challenges arose too. In many cases, teachers agreed with the principles of DAP but did not know how to implement them well in daily practice, and many teacher preparation programs at colleges and universities did not prepare teachers to implement DAP adequately. Moreover, a variety of misconceptions about DAP was prevalent, some of which still exist, as mentioned earlier.

Regardless of the criticisms, the idea of DAP gained momentum. It became positively and widely influential within the profession, and leaders set out to make improvements to DAP in response to current thinking, research, and societal contexts.

Revisions to Emphasize the Role of Teachers, Culture and Language, and Alignment

In 1997, NAEYC invited an expert panel and wide participation from the field in order to revise the position statement and book, both edited by Bredekamp and Carol Copple. It was in this version that NAEYC articulated that teachers should make learning "challenging and achievable." The editors explicitly stated that young children must be challenged to achieve new levels of learning but that teachers should set challenges to a level that a child could achieve with effort, rather than setting the bar at a level too high to achieve or too low so as not to stretch the child at all.

The 1997 revision increased the emphasis on content learning, planned curriculum, and assessment and underlined the importance of the teacher as an intentional decision maker in all these respects. Intentionality is now a central tenet of good teaching practices within DAP. With increased emphasis on the theories of Lev Vygotsky, who emphasized an active role for adults in children's cognitive and social development and learning, the 1997 revision emphasized teachers' intentional role in stimulating children and scaffolding to help children achieve new skills. (To scaffold is to guide children to build on emerging skills and interests through questions that extend children's thinking and through demonstrations, suggestions for alternate approaches, and so forth.) With this emphasis, the revised position statement highlighted the need for balance between child-initiated and teacher-guided experiences. It emphasized the holistic nature by which young children learn and added an emphasis on making practices *culturally* appropriate for children from all backgrounds, including respecting and encouraging dual language development. It also brought attention to inclusion of children with disabilities.

In 2009, NAEYC published the third edition of the position statement and book, based on input from a panel of nationally recognized experts and input from the field. Key points included the role of standards, new knowledge about learning trajectories, achievement gaps between groups of children and how DAP could help to close them,

and the need for continuity and alignment of children from prekindergarten through third grade. In addition to reiterating the centrality of relationships in young children's learning, the book provided a more refined discussion of play than had previously been provided. In the previous decade, research had shown the benefit of high-quality play—rather than all unstructured activity—to children's self-regulation and learning, as well as how to promote such play. In addition, this edition clarified the role of instruction, small- and large-group learning experiences, and teacher scaffolding. The book also included new research about children's executive functioning—that is, children's ability to think, plan, pay attention, make decisions, use logic, and problem solve—and how play and other activities promote executive functioning and self-regulation.

Revisions led to a series of NAEYC publications in 2013 and 2014 that included a book and DVD each on practices for (a) infants and toddlers, (b) preschoolers, (c) kindergartners, and (d) children in first, second, and third grades.

As a result of the wide distribution of the various DAP publications and their use in early childhood education programs and college-level teacher preparation programs beginning as early as the 1980s, the term *developmentally appropriate practice* entered the common lexicon. Parents, policy makers, researchers, and lay persons began to use the term, with recognition of the core ideas but with varying levels of accuracy.

Developmentally Appropriate Practice and Research

The obvious question about DAP for educators, parents, and policy makers is a pragmatic one: Are the practices outlined more effective in supporting young children than other practices? When the notion of developmentally appropriate practice was first articulated, researchers began examining that question. A number of researchers, such as Marilou Hyson, Diane Burts, Rosalind Charlesworth, and others, attempted to develop measures that captured elements of NAEYC's 1987 position statement on DAP, creating instruments such as the Classroom

Practices Inventory. These early studies typically did not control for selection bias or use random assignment, and there may have been unexamined selection bias as far as which families chose to use DAP-based programs; yet the early results provided a foundation of support to continue exploring the notion of DAP. For example, they showed that the DAP approach, in comparison to highly didactic approaches, correlated with less child anxiety and stress; higher levels of divergent thinking and creativity; better language outcomes, including higher receptive language scores and verbal skills; and greater confidence.

On the other hand, developmentally appropriate programs and highly didactic programs on average seemed to generate similar levels of cognitive and academic performance in areas such as reading, mathematics, and science. Importantly, however, the academic-outcome findings also captured a critical group-based difference: There was a distinct advantage in cognitive and academic performance for DAP programs for children from low-income and low-educational attainment families as compared to middle-class and affluent children. Other research also started to show that cognitive and academic results favoring DAP appeared longitudinally, even when they had not appeared in children's immediate outcomes.

Early measures such as the Classroom Practices Inventory over time came to be seen as unable to adequately capture various elements of DAP, and later research focused more on specific dimensions of DAP. Overall, few studies examine DAP as a unified entity as researchers began examining various dimensions of DAP (e.g., warmth of teacher-child relationships, balance of play and direct instruction) or specific educational models grounded in DAP principles and guidelines, such as HighScope, Tools of the Mind, and Creative Curriculum, as compared to other models. The results typically support the effectiveness of the various components of DAP for children's short-term (e.g., increased compliance, improved attention) and long-term (e.g., decreased grade repetition, improved cognitive scores) success and well-being. As a result of the consistent findings in favor of components of DAP, the term *developmentally*

appropriate practice is sometimes used interchangeably with the notion of high-quality early childhood education.

Major research handbooks have summarized the evidence, such as *From Neurons to Neighborhoods: The Science of Early Childhood Development* (2000), edited by Jack Shonkoff and Deborah Phillips; *Eager to Learn: Educating Our Preschoolers* (2001), edited by Barbara Bowman and colleagues; *Handbook of Child Development and Early Education* (2009), edited by Oscar Barbarin and Barbara Wasik; and *Handbook of Early Childhood Education* (2012), edited by Robert Pianta and colleagues.

Research on Blending Child-Guided and Teacher-Guided Activities

Research confirms that it is the blend of child-initiated, free-choice, playful activities *and* teacher-directed activities and instruction that helps children meet challenging but achievable goals. Emphasizing either approach at the expense of the other was shown by researchers such as Elizabeth Graue and colleagues in 2004 to decrease children's success over time. One classic study of the HighScope curriculum by David Weikart, Larry Schweinhart, and colleagues that began in 1967 compared the HighScope curriculum and another child-centered nursery school experience that blended children's active learning and intentional teaching to a highly scripted teacher-centered direct instruction experience. At age 23, the direct instruction participants had 3 times as many arrests and more emotional and other problems than their HighScope peers. Other studies have similarly shown that a balanced approach associates with children's higher language and literacy scores, math and reasoning skills, and strong social-emotional skills, both concurrently and longitudinally. These findings have been replicated in several other studies.

Research on Warm, Responsive Teacher–Child Interactions

A key aspect of DAP is the warm bond that a teacher has with the children, knowing them well as individuals and being responsive to individual

differences. Research, including studies using nationally representative samples, indeed confirms that positive teacher–child relationships correlate with other dimensions of DAP and with good child outcomes, including academic success, social competence, and fewer behavior problems. One widely used instrument measuring quality of early childhood and elementary classrooms (especially teacher–child interaction quality) is the Classroom Assessment Scoring System (CLASS), developed by Pianta and colleagues. Findings using this measure show that in programs where teachers have positive, responsive, and consistent interaction styles, children are more engaged, have better self-regulation skills, and achieve better social and academic outcomes. A strong body of evidence from numerous researchers unequivocally shows the centrality of teacher–child relationships in positive learning experiences and outcomes for children.

Linking DAP and Quality

With wide acceptance of the core elements of DAP, measures and studies have increasingly used the term *high quality* to capture the congruence of elements of DAP—in contrast to programs using push-down, highly didactic, or strongly teacher-oriented approaches. In an attempt to measure quality, simultaneously capturing core elements of DAP, researchers developed the Early Childhood Environment Rating Scale (ECERS) in 1980 and revised it in 1998 to reflect, among other things, NAEYC's refined explanation of DAP and program quality, including emphases on cultural diversity, family concerns, and children's individual needs. The ECERS and ECERS-Revised have been used in many major national and international studies, and researchers refer to programs scoring well on these measures as high quality. As another example, the Center for the Developing Child at Harvard University characterizes high-quality programs as those incorporating the basic elements of DAP, such as (among other things) opportunities for active and quiet play; developing motor, social, language, and cognitive skills through play; positive interactions with adults; practices that support

positive interaction among children; facilitation of emotional growth; engagement with families; and respect for diversity—all characteristics emphasized in DAP.

A growing number of large-scale studies from the 1990s onward confirm that children's best chances of experiencing success and well-being emerge through high-quality—that is, well-implemented, developmentally appropriate—practices in early childhood programs, especially for children from economically and otherwise disadvantaged families. Major studies confirming these findings include the Cost, Quality, and Outcomes Study, the National Institute of Child Health and Human Development Study of Early Child Care and Youth Development, Head Start impact evaluations, the HighScope Perry Preschool Study, the Carolina Abecedarian Project, the Chicago Child Parent Centers, and Oklahoma's universal pre-K evaluations.

Contemporary Research

Research from the 2000s and 2010s corroborate the earlier findings: High-quality developmentally appropriate programs are associated with good child outcomes. For example, the Quality Interventions for Early Care and Education study in 2013 found that programs in which teachers show sensitivity and provide a high quality of caregiving and teaching (core components of DAP) are associated with children's literacy, math skills, and emotional health, as well as with fewer problems such as aggression, hyperactivity, depression, and anxiety. Researchers concluded that program experiences aligned with DAP guidelines were the most consistent predictor of school readiness, emotional health, and fewer problems.

Similarly, a multistate study of 6,000 preschool and elementary children using the CLASS found that teachers' instructional support to children in preschool positively predicted concurrent prereading and math skills; teachers' emotional support in preschool contributed to social skills in kindergarten; warm teacher-child interactions correlated with kindergartners' self-control and engagement; and effective teacher-child interactions helped

at-risk first graders achieve the same degree of social and academic skills as other children. These and other recent large-scale studies indicate that what many consider the essential components of DAP (e.g., warm, reciprocal relationships and a balance of child- and teacher-guided activities) correlate with good child outcomes.

Developmentally Appropriate Practice Internationally

The articulated concept of DAP emerged in the United States, but DAP-based programs exist internationally and are expanding. In a review of 20 developed nations in 2002, Tony Bertram and Chris Pascal found striking overlap in terms of the values and practices in early education that essentially align with the core principles of DAP. The countries included in the study were Australia, Canada, England, France, Germany, Hungary, the Republic of Ireland, Italy, Japan, Korea, the Netherlands, New Zealand, Northern Ireland, Singapore, Spain, Sweden, Switzerland, the United States, Wales, and Hong Kong. Professionals across these countries generally agreed that early educators should

- include a child-centered, flexible, and individually responsive curriculum;
- recognize the importance of working in partnership with parents;
- offer broad and relevant learning experiences in an integrated manner;
- appreciate the importance of play and active, exploratory learning;
- emphasize social and emotional development; and
- empower children to be autonomous, independent learners.

Educators used different curricula (e.g., HighScope, Montessori, Reggio Emilia, Te Whariki) within the various countries, as one would expect, so that curricula matched respective contexts and cultures. What the curricula did not include was rote memorization or passive learning, long periods of sitting still, a highly teacher-oriented

approach, and other approaches DAP proponents would consider inappropriate.

In many developing nations where funds for and knowledge about early education are lower, awareness of DAP is only now emerging. Several types of misconceptions exist in developing countries—all of which are also true in developed countries as well, to varying degrees. Parents and professionals sometimes incorrectly perceive “formal” or didactic approaches as more serious and effective than perceived unstructured or play-based methods. Some may underestimate what young children are capable of and not see the value of early childhood education and stimulation. Still others may see early childhood as a time to play, be carefree, and stay close to parents, without recognizing that good early education programs encourage those things to occur. And some mistakenly associate DAP with the hands-off approach discussed earlier. These misconceptions hamper implementation of DAP-based programs.

Nonetheless, many developing and economically emerging countries already implement aspects of DAP or are interested in learning more about DAP. The DAP position statement and books have been translated into numerous languages. Research on DAP has been conducted in Cyprus, Greece, India, Hungary, Jordan, China, Ecuador, Korea, Cambodia, and elsewhere, and a growing number of countries are starting to incorporate DAP into existing early education programs. For example, in the mid-2010s, Saudi Arabia engaged NAEYC to help create developmentally appropriate program standards, Indonesia collaborated with the World Bank to support development of developmentally appropriate programs in poor districts, and Bangladesh worked with Save the Children to strengthen DAP-based early childhood practices. Leaders emphasize that how DAP is defined must be adapted to suit the context and values of a given culture, particularly for non-Western cultures, while retaining core values. For example, that children do not receive corporal punishment is true to DAP regardless of culture (a core value); however, whether a program uses time-out as positive discipline or whether boys and girls have class together may be culturally bound. Specific adaptation is

also a concern for children whose healthy development has been interrupted, such as children rescued from trafficking or who have suffered abuse, live in conflict areas, or have experienced natural disasters, whether within the United States or another developed country, or in a developing country.

Regardless of context and adaptations, the essential practices of DAP-based programs are consistent worldwide: Teachers create caring communities of learners, plan curricula and carry out assessment appropriately, engage with families, and implement other basic components of DAP.

Contemporary U.S. Trends and Policies That May Impact DAP

In the United States, DAP is the most prevalent and widely promoted approach to early childhood care and education for which experts advocate. The majority of early childhood researchers and educators advocate for implementation of DAP approaches for children from birth to age 8, or up to about third grade. At least two contemporary issues are likely to influence the implementation of DAP for children from birth through age 8 in the United States in the 2010s and 2020s.

Common Core State Standards

State leaders throughout the country established a common set of expectations in 2009 for what children from kindergarten through 12th grade should know and be able to do. Called the Common Core State Standards (CCSS), the standards name benchmarks but do not require a specific curriculum. Some early childhood and elementary teachers fear the standards will undermine use of DAP, particularly because initial standards focus only on language arts and mathematics. In addition, critics of the CCSS perceive national benchmarks as antithetical to teachers’ power to individualize learning for each child, a central requirement of DAP. Others, however, note that the standards emphasize thinking and problem-solving skills and that using DAP will only help children gain CCSS competencies. Whether

the CCSS derail DAP or increase the use of DAP, especially in the early grades of primary school, will depend on how well teacher preparation and training programs explain the relationship between standards and implementation of appropriate experiences and activities.

Universal Pre-K Initiatives and the Pre-K to Third Grade Movement

Oklahoma was the first state to offer public prekindergarten on a voluntary basis to all 4-year-olds in the state, followed by Florida, Georgia, and now several other states. About half of 3- and 4-year-olds in the United States attend preschool, and about one third of them are in a publicly supported program. Programs using public dollars are more likely than privately funded programs to have quality requirements based on DAP guidelines, as well as accountability measures that determine whether programs are using the most effective practices (i.e., DAP). As the availability of public pre-K rises, awareness and implementation of DAP is likely to rise as well. In addition, organizations, state leaders, and school administrators are working to better align curricula and teaching methods between levels of education from preschool to the early primary grades, which could raise discussion about best practices for children up through age 8. These initiatives may ironically lead to higher expectations for children's performance that some consider to be at odds with DAP unless all relevant stakeholders understand the principles behind DAP.

Conclusion

Other trends and issues, including conversations about closing achievement gaps for low-income children, the unique needs of and challenges for children in immigrant families, and the rise in childhood obesity and cuts to recess and physical education time, could also impact awareness of DAP. Collectively, these trends and policy matters will impact the degree of understanding educators and families have about what constitutes DAP. Yet research and practice will also continue to inform what constitutes DAP, which is not a static single

entity but a dynamic, multidimensional set of practices. As educational, neuroscientific, psychological, and economic research unfolds and converges with the long-standing strengths and emphases of the early childhood field, professionals will continue to discuss, debate, and refine definitions of various dimensions of DAP. The topic is likely to become increasingly relevant as early childhood gains stature on the national and international education stage, especially as leaders finalize decisions about universal access to comprehensive early childhood education within the post-2015 worldwide Sustainable Development Goals.

DIFFERENTIATED INSTRUCTION AND ASSESSMENT

Differentiated instruction is a teaching approach in which a teacher designs curriculum (i.e., what to teach) and instruction (i.e., how to teach) based on children's interests, developmental readiness, and learning needs. A teacher who adopts differentiated instruction as her teaching philosophy authentically assesses children's current knowledge and skill level, sociocultural background, and

special learning needs. Teachers use this information to plan learning experiences that would optimally challenge and elevate children to a higher level of ability and understanding.

This entry aims to inform the reader about differentiated instruction and assessment in the early childhood education context and to provide a concrete description of this approach and its implementation steps pertaining to education of young children. The entry begins with explaining the definitions of *differentiated instruction* and *assessment* and how the two concepts intertwine during the teaching process. It further illuminates crucial elements of differentiated instruction and assessment and, finally, outlines steps that early childhood teachers should follow in order to implement differentiated instruction and assessment to address and respond to young children's learning needs.

Definition of Differentiated Instruction and Assessment

Increasing diversity among children's culture, language, ethnicity, socioeconomic background, and individual abilities is observed across all levels of education including early childhood. Present-day early childhood programs are considered as the first step to schooling for children from birth through kindergarten. Therefore, early childhood teachers face the challenge and responsibility of adequately addressing very young children's varying learning needs and preparing them for what is to come in their educational journey. An effective response to this issue is to adopt differentiated instruction. Carol Tomlinson, who is a prominent teacher and an education researcher, has written extensively about differentiated instruction and assessment and has helped educators to understand this teaching philosophy. Although her work mostly focuses on elementary, middle, and secondary education, principles that she laid out shed light on the context of this entry, which focuses solely on early childhood education.

Principles of respect for individual children, acceptance of their different abilities, setting high standards for every child, and most important, a

passionate belief in every child's learning potential form the philosophical basis for differentiated instruction. Each child has different learning needs and levels of understanding and brings into a classroom his or her unique interpretation of the world. Through differentiated instruction and assessment approaches, teachers identify these differences and needs, assess proximity of each child to the curriculum goals and objectives, and design learning environments and experiences that support young learners.

Assessment, as a crucial part of differentiated instruction, is the process of gathering data on individual children's learning and development. The differentiated instruction approach, in the early childhood context, requires teachers to assess children systematically to be able to depict a strong and clear picture about children's learning interests, what prerequisite knowledge and skills they need to acquire to advance to higher levels of learning, and finally how children can most effectively learn and apply new knowledge and skills to new contexts. Assessment in an early childhood education classroom is conducted (authentically) on a daily basis through thoughtful planning. A teacher who implements differentiated instruction incorporates different assessment strategies such as divergent (open-ended) questioning; keeping anecdotal notes and running records through daily observations; applying checklists; collecting children's work samples; recording children in different learning environments via photography, audio, and video recording; and interviewing children and family members.

Utilizing data gathered from assessment, teachers design differentiated learning experiences for children. Learning often takes place in small group settings, in which children can comfortably express themselves in creative ways as well as receive immediate and individualized feedback from their teachers. A typical preschool classroom is set up around activity centers (blocks, dramatic play, art, manipulatives, reading and writing, science and discovery, sensory, gross motor, etc.), where children are involved in small group learning. A low teacher-to-child ratio provides teachers with time

to rotate among activity centers to observe children's development and progress as well as scaffold their learning. Such settings encourage independent decision making as to which center children can choose as well as presenting teachers with opportunities to observe children's varying knowledge and abilities on different tasks.

In summary, differentiated instruction and assessment are two intertwined procedures of early childhood curriculum and instruction, and thus they reciprocally inform each other. Teachers use this process to improve learning environment for children and design more effective learning experiences for them. A teacher who utilizes differentiated instruction incorporates assessment of learners in every step of the teaching and learning process.

Core Elements of Differentiated Instruction

This section focuses on four core elements of differentiated instruction in the context of early childhood education: content, child, teacher, and learning environment.

Content

Teachers who adopt differentiated instruction and assessment organize early childhood education curriculum based on careful observation of children's interest areas as well as the social context in which they live. A developmentally appropriate curriculum centers around overarching themes to allow children to study a big idea with its different components throughout a time span. In that sense, the project approach and emergent curriculum fit in the description of such curriculum. Through a project approach, teachers organize various levels and layers of learning activities. These learning experiences present a continuum and are connected to children's existing knowledge and skills as well as the social-cultural background they come from. Consequently, a meaningful content that is connected to children's lives increases level of engagement, attention, and motivation during the learning process.

Teachers can integrate different subject matter areas (e.g., literacy, art, science, math, social studies) throughout project methods, therefore providing a range of rich learning experiences from which children can freely choose. For example, "transportation" as a central curriculum theme is very familiar to young children. Children can explore different means of transportation used in their community (social studies), practice traffic safety rules (health and safety), create rules for their own classroom (literacy), and design a school bus out of a large cardboard box (science, math, art). Such range of activities designed for children contributes to more than one developmental domain (e.g., cognitive, language, social-emotional, and physical) and subject matter area (e.g., social studies, health and safety, science, math, art, literacy). Furthermore, children integrate different sensory areas of their brain, which in turn increases the brain activity and strengthens neural connections.

As they implement differentiated instruction, teachers design learning activities by keeping children's learning needs in mind. For example, visual traffic signs could be easier to follow and grasp for some children, whereas tactile learning opportunities such as taking apart and putting together a toy truck could be more appealing to others. Howard Gardner's multiple intelligences theory serves as a guide for early childhood teachers who strive to understand how children's intelligences work and the different ways in which children learn and interpret knowledge. Observation and assessment of these individual learning preferences are crucial to planning and implementing a developmentally appropriate curriculum for young children.

Child

Early years are perhaps the most unique time in human life in which development changes most rapidly. Children's development in preschool years (ages 3 to 5) varies so greatly that a teacher is likely to have a range of ability levels in his classroom. For example, one 4-year-old may recognize all letters of the alphabet, whereas another

4-year-old may already start writing her full name. This variation in language and literacy development can only be identified through authentic assessment of children's abilities. Pre-assessment of children's abilities and skills allows teachers to identify children who have similar levels of development and a common learning pace. Teachers can therefore organize activities that will appropriately challenge and advance them in those areas. Continual assessments and post-assessments help teachers monitor children's progress closely, measure if the curriculum and instruction implemented respond to children's learning needs, and make necessary accommodations for different learning groups. Pre-assessment data help teachers to determine the appropriate learning goals and objectives for children. The most crucial part of choosing learning goals and objectives is adopting a strengths-based approach and accepting each child as a capable individual instead of focusing on each child's deficits.

Even young children have a preference and area of interest as they explore different concepts. Through differentiated instruction, teachers build on children's interests and extend the children's learning to other content areas. Children who are involved in learning experiences that are appealing to their interest and learning style will develop love for learning early on, which will affect their schooling in later years. In fact, research has shown that children who are engaged in meaningful and active learning experiences in early childhood are more enthusiastic toward learning new subjects, more motivated to take on new learning tasks, and, in turn, have higher academic performance.

Through differentiated instruction, children receive encouragement and guidance from their teachers. They gain confidence in solving problems, take initiative to explore content, gain responsibility, and learn democratic skills. For example, teachers can involve preschoolers in creating a set of classroom rules at the beginning of the school year. Each child's opinion is valued and respected equally. The group votes on the most important five rules, and children can have a voice as well as learn respect for others' opinions.

Teacher

An early childhood teacher's teaching philosophy and dispositions about educating young children shape the teacher's relations with students, his approach to planning and implementing curriculum and instruction, his way of organizing learning environment, and, most important, how he supports students' learning.

Positive relations with children lay at the core of differentiated instruction. Warm and reciprocal relationships established in the classroom allow children to act and express themselves genuinely. Having conversations during daily routines such as mealtimes or cleaning, participating in children's play, or simply being present help teachers gain an understanding of what each child is capable of and what strengths the child has. Differentiated instruction requires teachers to look at children from a responsive perspective (instead of a more common deficit perspective) in which teachers recognize children for their unique abilities and strengths rather than their challenges and insufficiencies.

An effective teacher builds on children's self-esteem and positive self-concept by encouraging them to demonstrate their strengths as well as to set up simple steps to complete challenging tasks. For example, a 4-year-old preschooler may still have difficulty with one-to-one correspondence of numbers up to 5, yet the same child can identify and label complex geometric shapes such as a trapezoid. A skilled teacher carefully observes and meets this child where he is in his cognitive skills. The teacher integrates three-dimensional objects in the manipulatives center as she helps the child count all the sides of a shape in order to help him make a connection between single-digit numbers and how those numbers are used to represent objects.

The teacher is aware that all students deserve a right to quality early childhood education in order to acquire fundamental knowledge and skills that are necessary for their future academic progress. He respects every child in his classroom as well as children's families regardless of social, cultural, ethnic, linguistic, and economic background. Teachers who adopt differentiated instruction

create a democratic learning environment in which children have a voice and opportunity to make independent choices for their learning.

The first and utmost important task a teacher performs in the parameters of differentiated instruction is the pre-assessment of each child's existing knowledge and skills. Information gathered through this process allows a teacher to meet children where they are developmentally and then to organize learning experiences around the children's level of understanding and abilities. The teacher establishes an ongoing assessment process in his classroom to monitor children's progress and uses the assessment data to appropriately respond to children's learning needs. He also constantly assesses his own teaching and reflects on what works best and what needs to be improved in his instructional style as well as planning curriculum and learning environment. Such ongoing assessment and reflection cycle increases the quality of education and benefits young children.

An early childhood education teacher who adopts differentiated instruction as his teaching approach sets up high standards for every student in his class, including children with special needs. The teacher selects learning goals and objectives appropriate for children. These learning goals and objectives are based on empirically based child development knowledge, pre-assessment of each child's knowledge and skills, and social-cultural background. Early childhood education teachers utilize early learning guidelines that their respective state adopted. These standards are aligned with each state's K–12 learning standards in order to create a continuum throughout children's schooling experience. The early learning guidelines stretch through a wide behavior spectrum (e.g., cognitive, language, social-emotional, and physical) considering the great variation in learning and development in early years of life and, in turn, provides a flexible framework for teachers to adjust their instruction for individuals or groups of children in their classrooms.

Adopting learning goals and objectives for children helps teachers anticipate certain outcomes and advancement in children's skills and prepare appropriate learning activities. For example, a

teacher is aware that a typically developing young preschooler (3 to 4 years old) can name some of the letters in the alphabet, whereas an older preschooler (4 to 5 years old) can recognize most of the letters in the alphabet. Therefore, this teacher would explicitly point to the beginning letters and sounds of words during a book reading activity. Keeping in mind learning objectives, this teacher guides and scaffolds children's learning through asking thought-provoking, open-ended questions and promoting divergent thinking.

Learning Environment

When organized effectively, a classroom environment becomes a second teaching agent for children. Early childhood education classrooms are organized based on activity areas such as blocks, manipulatives, dramatic play, reading/literacy, writing center, discovery, and art. A theme-based content curriculum with its learning activities and materials is infused throughout these centers. As children rotate among different learning centers, they find opportunities to engage in solitary as well as small and large group learning.

Learning materials integrated in a learning environment adopting differentiated instruction are appropriate for children's developmental as well as learning needs, neither too challenging nor understimulating. A range of learning tools is easily accessible for children in order to promote independent decision making and responsibility for their learning. Materials that are open-ended in nature and promote creative and critical thinking in children are the most appropriate ones because they promote learning through trial and error and integrating multiple senses.

Such a learning environment is child centered, meaning that the activities and materials are chosen carefully and considerately to help children meaningfully make connections between what they already know and are capable of and what they encounter in a learning environment. To prepare a child-centered learning environment, teachers authentically observe children's existing abilities and knowledge level, subjects that they are interested in, and specific learning needs that they are expected to

meet. Open-ended activities and materials provoke thought and wonder in children. A great example of this process can be observed in Reggio Emilia early childhood programs that originated in Italy and are based on the idea that children's interests and curiosity in the world surrounding them should be the leading force behind the curriculum and instruction designed for them.

The classroom schedule is flexible enough to allow children space and time to practice newly acquired skills and also expand to new ideas and thoughts. Furthermore, a flexible schedule enables teachers to attend to small groups of children, observe and monitor children's progress, guide their learning, and give feedback on their actions.

Steps to Implement Differentiated Instruction and Assessment

Effective implementation of differentiated instruction and assessment in an early childhood context proceeds through the following steps:

1. Conduct a pre-assessment of children's existing knowledge, skills, and experiences. Teachers must first see where children in their classroom are developmentally and academically. To gain this understanding, teachers conduct authentic assessment methods and gather objective and clear information to know each child in their classroom.

2. Select concepts that are appealing to children's interests and the social-cultural context in which they live. A project-based curriculum approach has been proven to be a very beneficial curriculum method with young children.

3. Set up clear learning goals and objectives that are developmentally appropriate for children. This process almost goes simultaneously with the pre-assessment process, which helps teachers identify the goals and objectives targeted by the curriculum.

4. Plan learning experiences. Pre-assessment of children's knowledge and skills, their individual interests, and learning goals and objectives that are set up accordingly are major determining factors in

the kind of activities teachers plan for children. Learning experiences that appeal to different intelligence areas and integrate different sensorial and brain regions are more meaningful and more likely to be recalled by children in the long run.

5. Conduct ongoing assessments and post-assessments of children's progress and teacher's curriculum and instruction. Teachers continually assess children's progress and make adjustments to the learning environment, learning experiences, and the instruction provided. A post-assessment of children's progress allows teachers to see whether children were able to accomplish the goals and objectives aimed for them. Teachers also reflect on their instructional performance to evaluate whether the curriculum and instruction, assessment methods, and the learning environment effectively responded to children's learning needs.

In conclusion, differentiated instruction, along with authentic assessment, aims to increase effectiveness of curriculum and instruction provided in the class and meet the learning needs of individual children.

DIFFERENTIATION

Differentiation or differentiated instruction (sometimes referred to as DI) is the adaptations or changes made to instruction in order to meet all learners' needs. This entry describes the reasons for differentiation in early childhood education and how to create differentiated instruction in the classroom.

Rationale for Differentiation

Differentiation is based on the philosophy that all children can learn but each child is unique and learns at his or her own pace. Instruction is not one

size fits all, and very young children—even if they are all the same chronological age—can span a range of developmental milestones. It may also be important to note what differentiation is not. It is not a different program of study for each student (this would be an individualized education plan or program [IEP] for a child with a diagnosed special need and is not always possible). Children have varying experiences, ranges of interest, and abilities and come from different family and cultural backgrounds. In inclusive classrooms where typically developing children and children with special needs are educated together, differentiation becomes a staple for classroom teachers, helping them to teach a room full of children all at different levels with varying degrees of need. Because one way of teaching will not meet all children's needs, differentiated instruction allows educators to create one flexible lesson plan to meet all children's needs. Teaching is successful only when children learn or show progress. Success does not mean that all children get the same instruction, but each student gets what he or she needs. Because not all children start in the same place and not all children will progress at the same pace, a varied form of instruction is essential regardless of special need.

This philosophy and best practice in early childhood education require teachers to know children and families well. Knowing where students are, where they are starting, and their interests and cultural frameworks will enable teachers to create differentiated instruction. Baselines, screenings, home visits, and other authentic forms of assessment are used to determine where and how to start instruction. Then teachers use this information to design instruction for their class. Differentiation is not easy and requires a lot of time, planning, and training. It is often difficult to keep instruction, assessment, and curricula developmentally, individually, and culturally appropriate. Because differentiation can be misunderstood, teachers benefit from professional development.

Creating Differentiated Instruction

Differentiation and developmentally appropriate practice (DAP) are grounded in meeting children

where they are and taking into account each child's level, interests, culture, and ability. Differentiated instruction can be adapted in four major ways to meet learners: content, process, product, and environment. Each area of differentiation, when intentionally implemented, can ensure all children have access to teaching and learning.

Content can be differentiated by addressing the overall major goal or outcome desired. Reviewing the objective and scaffolding the prerequisite skills needed to get to this goal will assist students not quite ready to move on. When teachers know students well and understand pedagogy, this type of differentiation can be address based on the child's current baseline or skill level. Once established, the sequence can be followed to adapt content needs and final objectives. Differentiating for content requires frequent assessment and progress monitoring to be sure the overall objective will be met.

The most frequently used example of content differentiation is leveled readers. This allows children to read about the same topic or practice similar literacy skills while interacting with text at their own level. When differentiation is based on process, the teacher considers how the children are going to meet the required objective. Rather than one prescribed way, there may be many pathways to meeting this objective or skill. Consider other ways the child could ultimately arrive at the same goal but use a different way to get there. Frequent and varied attempts, including kinesthetic, verbal, musical, spatial approaches, and so on (consider Howard Gardner's theory of multiple intelligences) are ways to meet the required objectives. Some students may require more time on task, various active ways to respond, picture cards instead of verbal responses, and so on. Students' interests should be considered.

The product can be adjusted to show growth or learning. The final product or final evidence used to show the objective has been met can be adjusted to best fit the need of individual children. Here the child should be allowed to show what he or she learned in the best way possible. The child can express his or her own learning in various ways.

The environment can be adapted to ensure all children have access to materials and activities.

Universal design for learning (UDL) has its roots in architecture, where buildings are designed with ramps, elevators, and curb cuts. These building features allow citizens in wheelchairs access to the building but these features, although designed to assist people with special needs, also benefit mothers with strollers and deliveries made on carts. UDL provides children with special needs access to the classroom and materials but also benefits all children.

Differentiated instruction is not tracking students, forming fixed grouping for instruction, or labeling children. Differentiating instruction requires teachers to create flexible lessons by adjusting the content, process, product, or environment for one lesson. All children learning together can participate in instruction based on the adaptations or changes made by the teacher for this specific group of learners.

DIFFICULT TEMPERAMENTS, CHILDREN WITH

Children are born with certain characteristics that influence how they respond to their environment and the people in their world. These traits, often referred to as temperament, are the cornerstones of a child's personality and will determine how the child approaches and responds to the world around him or her. This entry explains what is meant by the term *difficult temperament* and discusses strategies that can be used to support children with difficult temperaments.

Temperament can be determined by observing a child's behavior. There are three categories traditionally used to describe a child's temperament: easy, slow-to-warm up, and difficult. A child described as easy will be able to go into different settings without getting anxious or upset, whereas a child described as difficult might cry and scream whenever a new person, setting, or activity is introduced to her. These categories are simply descriptive of how a child responds within certain environments and should never be used to determine whether or not a child is "good" or "bad."

It is estimated that approximately 10% to 20% of all children have issues that can be described as difficult temperament. Traits associated with difficult temperament include the following:

- Impulsivity
- Hypersensitivity to sensory stimulation (noise, temperature, smells, etc.)
- Resistance to changes in daily routines
- Anxiety and fear in regard to new activities
- Easy distractibility
- Inability to calm down when agitated
- Irregular sleeping and eating patterns
- Intensive mood swings resulting in "acting out" or completely withdrawing from social situations

Such behaviors can be difficult at times for parents and teachers. However, a child with difficult

temperament can learn coping strategies to help him deal with these issues. If he does not learn how to manage his own reactions to things, he is likely to become confused, frustrated, and angry. In addition, he will receive negative feedback, which results in low self-esteem and a sense of failure. It is important for teachers, as well as parents, to develop attitudes, guidance strategies, and communication skills that will enable a child with difficult temperament to be successful, cooperative with others, and able to adjust to new environments.

The following strategies are designed to help parents and teachers provide support for a child with difficult temperament.

Use consistent routines that incorporate taking care of basic needs. For example, make sure the child has plenty of rest and eats nutritious meals low in sugar and high in complex carbohydrates. If at all possible, establish regular bed time routines that include time for reading, snuggling, and relaxing before going to sleep.

Always tell the child what is going to happen next. A child with difficult temperament does not like surprises. If there is going to be a change in routine, such as not going to music time or not going outside, tell the child and allow him to have time to process that information.

Establish environments that are sensitive to the sensory needs of the child. That means providing a place where she can go to take a "break" from the noise in the classroom. It is also important to monitor the temperature of the classroom, the noise level, and the overall sensory stimuli bombarding the child.

Encourage self-awareness and self-management of behaviors. For example, if a child is going to go to a new place, talk about it with him before you go. Describe what he will be doing, who he will be seeing, and what demands might be placed on him in that setting. Comment when you notice that the child is reacting strongly to environmental stimuli. For example, "You spit out your chili. I bet it was too spicy for you to eat. Next time tell me if your food is too spicy and I will get you something else."

Describe for the child positive behaviors you see in others that you would like for the child to emulate. If you notice two children sharing, you might say, “Look, Sarah is sharing her book with Dion.”

Give instructions one at a time. A child who is easily distracted has considerable difficulty remembering more than one thing at a time. It is possible that he will become frustrated if he is asked to do several things at once.

Plan transitions that encourage positive behaviors. Transitions are frequently times when a child with difficult temperament will have issues or get upset. Remember to tell the child a few minutes before it is time to change activities so she can process the information. In addition, transitions that are fun, such as flying like airplanes, hopping like a rabbit, or humming a song, can make a child feel more relaxed.

Remain calm when outbursts or tantrums occur. For example, say things like, “Please speak softly, there are others trying to work,” or “Take a deep breath and tell me what has upset you.”

Social skills can be taught through modeling and positive peer interactions. Work on behaviors such as negotiating a dispute with a peer, sharing a favorite toy, inviting others to play, asking others if you can join their play group, offering to help others, and calmly communicating your needs.

Provide choices whenever possible. Although you want to offer a child only two or three choices (too many can be overwhelming), it is always a good idea to ask a child what he prefers. This can be as simple as asking if he would rather play with blocks or play with puzzles, or if he would rather eat corn or green beans for lunch. It is, however, important to recognize that some choices can’t be offered, such as whether or not to put on a coat when the weather is cold.

Conclusion

With consistent routines, teachers and parents who remain calm when the child gets upset, and

environments that do not overstimulate, a child with difficult temperament can be successful in the classroom and at home. Remember a child with difficult temperament may be confrontational, so choose your battles wisely and avoid power struggles. The most effective strategy for working with a child with difficult temperament involves being proactive rather than reactive. Being proactive means that you recognize what triggers undesirable behaviors and you try to eliminate those elements from the child’s environment or adapt the environment in a way that elicits a positive response. For example, if you recognize that Carl gets upset when you ask him to put up his blocks, you adapt the environment by giving him extra time to finish building with his blocks.

When outbursts and setbacks do occur, it is important to use age-appropriate consequences. If at all possible do not raise your voice or threaten consequences that you can’t implement. By remaining relaxed and matter-of-fact, the child will eventually calm down. By partnering with the child’s family to implement consistency in routines and daily activities at home and at school, a child with difficult temperament can be successful and learn to self-manage his or her behavior. In the event a child continues to have difficulties, there are clinics and psychologists who specialize in working with a child who presents severe behavior challenges.

DIRECT INSTRUCTION

Direct instruction is an approach to teaching that is teacher-directed and emphasizes well-planned lessons in which the skills taught are broken down into small units and are explicitly taught in a systematic way. Direct instruction can be used individually with children, in small groups, or in large groups. Research shows that direct instruction can be effective in teaching a wide range of skills, particularly basic foundational skills, in early childhood education.

Direct instruction is based on the philosophy that when instruction is clear and free of misinterpretations, children's learning can improve at an increased rate. Rooted in behavioral theory, direct instruction evolved from the idea that behaviors learned are those that result in favorable consequences.

History

In the 1980s, a series of experimental studies conducted by many different researchers trained teachers to use different teaching strategies and then assessed the effects on children's learning compared to children who were not taught by teachers using those strategies. Common elements of the teaching strategies were identified, including teaching in small steps with student practice after each step, guiding students during initial practice, and ensuring that all students experienced a high level of success. Sometimes referred to as systematic teaching, explicit teaching, or active teaching, the term *direct instruction* was established in 1986 to describe these practices.

Key Components

While there are variations of direct instruction, this structured, teacher-directed approach includes several key components. These components are as follows:

- Materials and curriculum are broken down into small learning increments organized in a prerequisite order.
- Explicit step-by-step teaching and presentation of the material to the child is provided.
- Frequent opportunities are given for children to respond and practice with each step.
- Feedback is provided after each practice opportunity through reinforcement or error correction.
- Clearly stated objectives in terms of learner outcomes or performance are set for the child to master.
- Teacher-directed activities are gradually decreased so that children can have additional opportunities to practice skills with increasing independence.

Direct Instruction Models

Behaviorally Based Models

The initial direct instruction model was developed in 1966 by Carl Bereiter and Siegfried Engelmann and consisted of three stages: (1) introduction to the new content to be learned, (2) an interactive and scripted presentation of the lesson, and (3) guided practice with immediate feedback that is first teacher-directed and then shifts to independent practice that is closely monitored by the teacher. Programs evolving from these models include DISTAR (Direct Instruction System for Teaching Arithmetic and Reading), Project Follow Through, and the Tucson early education model.

Effective Teaching Models

In the 1970s, the initial models were refined into "effective teaching" models with the following three stages: (1) some type of opening activity, (2) the main lesson presentation, and (3) opportunities

for practice. Specific examples of these models include Barak Rosenshine's explicit teaching model, Thomas Good and Douglas Grouws's strategies for effective teaching model, and Madeline Hunter's design of effective lessons model.

Expository Teaching Model

The expository teaching model builds on direct instruction and focuses on time and control to help children learn concepts, principles, generalizations, and rules. Teaching procedures begin with activating children's prior knowledge to then help develop definitions of the new concepts that make sense to them. Children actively participate in activities and provide their own examples to promote practice and receive immediate feedback.

Research and Misconceptions About Direct Instruction

Research has shown direct instruction to be highly effective for teaching young children. Specifically, when designed and implemented correctly, direct instruction is useful in maintaining time on task as well as the learning and/or performance of new skills. Furthermore, research also indicates that direct instruction can be particularly effective in teaching young children with special needs.

There are several common misconceptions about direct instruction. These include that direct instruction is a lecture approach, when in fact it is an instructional model that focuses on the interaction between teachers and children. In addition, some believe that teachers can only choose one approach: direct instruction or free play. But direct instruction versus free play is a false dichotomy. Both direct instruction and free play have roles in high-quality early childhood education. Early childhood educators can use developmentally appropriate practices to determine how to balance and use both direct instruction and free play in the classroom.

DISPOSITIONS

See Professional Dispositions of Early Childhood Educators

DIVERSITY IN EARLY CHILDHOOD EDUCATION

Wherever we are, life in today's society is an unparalleled journey for everyone, but especially for children. Growing up in a society where changes are rapidly happening and new paradigms are being defined, the early childhood years unfold in an environment filled with excitement and also with challenges never before experienced. Within the context of the 21st century, the landscape of childhood is characterized by experiences in a society where every facet of diversity is present. In communities across the United States, the voices of children speaking in many languages with cultural roots in places local and distant, playing alongside peers with different views and abilities, tell the unfolding reality of early childhood education today.

Diversity, the Reality of Human Life

As a descriptor of human experience, emphasis on diversity has brought attention to the range of characteristics portraying people. Individual reality is influenced by the lens of diversity, where traits such as culture, ethnicity, language, abilities, age, religious beliefs, gender, and social and economic circumstances play a significant role in shaping ideas and behaviors. Diversity traits serve as the filter through which people approach and respond to life events. From the early years, a person's characteristics and unique experiences impact one's views and ideas shaping individual identity. Lack of understanding and unfamiliarity about realities diverging from those of their own, however, sometimes lead to prejudiced and unfair practices toward people, which has also spilled out into education. Today, misconceptions and lack of understanding about other realities still

challenge society and call for actions to ensure socially just educational services and programs for all. These actions must begin in the early years underlining the important focus on diversity in early childhood education.

Current efforts in early childhood education in support of fairness and equity follow the pursuit for recognition of diversity and implementation of culturally based education practices. Through the multicultural education movement, educators and leaders have worked for many decades advocating for the rights of all children. Multicultural education in the early years has brought attention to the role that individual experiences and cultural heritage play in the development and education of a child. This emphasis continues today.

Acknowledgment of people's multiple diverse realities has influenced the global social and political agenda. It has also uncovered the existence of inequalities, bringing forward the need for leading efforts in all aspects, particularly in education. Although the rights of all children are recognized today, reality still shows serious disparities in availability of educational programs and in the quality of learning experiences. Statements from the United Nations Educational, Scientific and Cultural Organization (UNESCO)'s *Incheon Declaration—Education 2030* (UNESCO, 2015), indicating that “no education target should be considered met unless met by all” (p. 2), reaffirm the pressing need for ensuring parity in services for every child. It also discloses the fact that access to equitable educational experiences is one of the markers society still aims to achieve, as stated in the United Nations Children's Fund (UNICEF)'s *The State of the World's Children 2015*. Today, despite a greater attention to diversity, much is still to be done in the overall societal arena. The plea for equality continues as an assertion of the rights of children to obtain and enjoy quality educational experiences. This establishes direction and sets the agenda for diversity for young children.

Diversity in the United States

In the United States, a nation with origins rooted in immigration, diversity is a denominator surfacing in

every aspect of social life. U.S. society has showcased the many cultures of people who came during the past, and continue to arrive today, in search of opportunities. Diversity has become not an isolated detail but rather a pattern describing people across the country. With demographic projections denoting an increased level of racial and ethnic diversity by the year 2060, U.S. Census reports foresee cultural plurality becoming the main societal descriptor in the United States. Among other factors contributing to the growing diversity in the United States, the steady flow of immigration that once gave place to the origins of U.S. society is predicted to remain one of the main forces. Societal challenges and political unrest, along with war and conflicts in other parts of the world, have forced many families to leave their countries, seeking better opportunities in the United States. The result is the rising presence of immigrant families and young children with diverse linguistic and cultural roots in classrooms across the nation.

Addressing Diversity in Early Childhood: The Legacy of the Past

The path leading to early childhood policies and practices addressing diversity has been a long journey that continues today. Although social and cultural diversity has always been present in U.S. society, recognition of the rights of individuals with diverse backgrounds and cultures evolved out of milestone efforts of leaders such as Dr. Martin Luther King Jr., who advocated for the equal needs of individuals during the civil rights movement. The work of these leaders upheld the rights of all people beyond social or individual differences and brought changes to education evidenced by the different laws and programs adopted. Programs such as Head Start and Early Head Start were created in response to the needs of children from socioeconomically challenged groups and from cultural and ethnic minorities, according to Edward Zigler. Laws mandating services and programs for young children with special needs recognizing their rights to quality educational experiences were also enacted during this time.

Emphasis on multicultural education practices and experiences brought attention to the diversity of cultural realities of children and communities, while anti-bias approaches have spurred the integration of social justice concepts as part of children's learning experiences. Yet, despite what has been accomplished, the need to emphasize the diverse reality and needs of culturally and linguistically diverse children, irrespective of their unique traits, continues today as one of society's challenging tasks.

Current Diversity Realities in Early Childhood Education

The global community in recent decades has seen dramatic social and economic changes. This has also been the case in the United States, where the impact of changes on families and children is evidenced in classrooms and programs everywhere. Social and political struggles have led to a continuous flow of immigrant families, particularly those of Hispanic roots, transforming the landscape of the country and underlining the need for attention to their cultural and linguistic realities.

Growing up in a culturally and linguistically different environment, immigrant children are challenged to adapt to other lifestyles and language to successfully gain membership into their host society. Spanish-speaking young children draw attention to current language and literacy strategies, reigniting arguments on linguistic practices for children acquiring English as a second language. Already the largest ethnic group in the United States, according to the U.S. Census Bureau (2013), Hispanic families and children have brought to the forefront the reality of language diversity of other ethnic groups with primary languages other than English, evidencing the pressing call to redefine and establish appropriate linguistic policies. Innovative policies and legislation, similar to that of Florida's Consent Decree, that affirms the rights to equitable educational practices of culturally and linguistically diverse individuals, are still needed to guarantee equitable and developmentally sound practices. Practices and approaches

on preservation of heritage languages emerge as a challenge making the case for redefining the nature of practices for children who are dual language learners, according to Eugene E. Garcia and Ellen C. Frede.

From a sociocultural perspective, the early years are the time when children's cultural identity starts to surface. Language plays a central role in this process, helping to connect individuals with their heritage. Immigrant children growing up in a society where the language and culture diverge from their own find this is a challenge, many times implying the loss of their sense of cultural heritage, especially as their home language fades away. Developmentally based pedagogical efforts are needed and must be responsively aimed at supporting heritage and promoting successful dual language development.

The reality of families and children, across social and ethnic groups, living in poverty conditions is present in early childhood classrooms. In recent times, economic challenges and a weak employment market have contributed to an increase in poverty in the United States. Poverty, another dimension within the spectrum of diversity, demands understanding of the everyday reality experienced by families who struggle with limited resources. Thoughtful consideration of the multifold nature and reality of poverty is critically needed to ensure respectful early intervention services and practices toward family and child. From the standpoint of equity, allocation of funding to create and extend comprehensive programs and services remains essential. Effective and proper coordination among agencies is needed to reach out to children and facilitate ways for their families to overcome their challenges.

The influence of easily accessible media on young children may have facilitated their awareness of social and racial tensions, raising the urgency of action to prevent formation of inaccurate ideas about people. This has elevated the need for classroom experiences with deliberate integration of multicultural practices and strategies addressing diversity and promoting social justice awareness in the early years. Intentional efforts are essential to counteract misleading ideas and

promote appreciation for diversity and support nonbiased attitudes and behaviors.

Writing the Agenda on Diversity for Early Childhood

The agenda for addressing diversity today emphasizes the need for a clear understanding of the diverse cultural character of society and of the responsible actions needed to provide for the needs of children with diverse backgrounds. Life today in most communities means interaction with a multiplicity of cultures and people's distinctive traits, traditions, behaviors, and ideas. Given that this is the milieu where young children grow and develop, greater understanding of the influence of the environment and the role that culture plays must guide practices in early childhood education.

With an early education stance based on responding to what is developmentally and individually sound, the action agenda for young children must be anchored in their cultural and life realities and in the responsibility society has for their preparation for future life success. Among the main implications of this posture is making certain that educational decisions and policies are made with thoughtful consideration to the fact that a child's developmental path is inherently influenced by the child's culture, individual experiences, and interactions.

An Action Agenda for Today and Tomorrow

The diverse realities of families and young children prompt a call for socially just practices. It also delineates the tone for the early childhood action agenda. Although landmark developments and legislation on behalf of young children have taken place, the struggle toward accomplishing the goal of equitable educational practices continues. Critical to any considerations on appropriate responses to diversity is to approach early childhood programs and practices from the perspective of what is individually distinctive and unique to children. Rather than focusing on their differences,

decisions and actions on behalf of children must begin with an appreciation of their uniqueness whether cultural, linguistic, or any other diversity feature. This positive and child-centered stance directs us to value the landscape of heritage and experiences children and families bring into the classroom. Developmentally, it underlines the relevance of their cultures, interactions, and life events as a guiding element in educational decisions and practices. Deliberate and committed efforts toward developmentally and culturally based practices are critically relevant for early educators.

Within the paradigm of diversity-based practices, several concerns continue to challenge educators and policy makers, such as access and availability of services and programs, equality and fair practices, and pedagogically culturally responsive practices. Despite efforts from all sectors, the issue of access continues to challenge schools and agencies still facing how to guarantee that all groups receive and participate in the programs and services available. A multifold issue, it underlines the need to eliminate barriers hindering participation along with actions to secure the existence and availability of programs and services for families and children. The problem of program availability is yet to be overcome, particularly in economically challenged communities and in areas characterized by high numbers of immigrant families. Efforts are needed to avoid exclusion of those who have been marginalized because of race, culture, language, and other diversity factors. Removal of these barriers remains an urgent challenge, particularly in communities where lack of well-coordinated efforts and responsive communication strategies continues to diminish participation in services and programs. The issue is especially critical given the increased number of families and children living in poverty and of immigrant children and families with languages other than English and who, in many cases, are not familiar with the education processes in their newly adopted communities.

Culturally responsive and child-centered pedagogy is another critical item in the agenda for action. Considerations about teaching practices

emerge as a vital element given their influence on the child's development and potential for individual and future school success. The need to reenergize curricular experiences with the perspective of children's realities is critical as early childhood education continues to evidence the multidimensional nature of society and life experiences. Central to appropriate teaching and learning practices is the intentional integration and validation of the cultural experiences and ideas of children and families from diverse backgrounds. Emphasis on pedagogical experiences centered on what is familiar to children and reflective of their cultures effectively meets the goals of education for diversity, creating interest and leading children to learn about themselves and their peers in ethnically and culturally diverse classrooms.

From the perspective of social justice, equality and fair practices remain a challenge, especially as educators ponder how effectively early childhood education addresses the realities of families and children. The clamor for equal and high-quality early childhood programs across communities is clearly heard. With research findings revealing the effect of quality experiences on children's overall learning, efforts and programs must be guided by the parameters of quality early childhood practices. Central to attaining quality is preparation of professional early childhood educators who are knowledgeable about pedagogical practices and culturally competent to responsively address children's unique needs. Integral to achieving equality and quality is the issue of funding and resources allocated to programs that will also contribute to reducing disparities in programs and resources available for children and families across diverse communities.

Children in today's classroom are an everyday living testimonial defining the early childhood diverse community landscape. Projected social and cultural changes call for new policies and innovative practices to responsively tend to the needs of children in schools across the nation where so many classrooms already mirror the world's diversity. Responding to diversity and its call for culturally sensitive practices remains the challenge for early educators and society at large

if they are to fulfill the promise of equitable and fair education for all.

DIVISION FOR EARLY CHILDHOOD

The Division for Early Childhood (DEC), founded in 1973, is a nonprofit organization whose members include teachers, therapists, family members, and others who care for, or work on behalf of, children birth through age 8 with special needs, and their families. Children with special needs include those with disabilities or developmental

delays and those at risk for future developmental problems. The DEC has two main purposes: (1) to identify and encourage use of evidence-based practices that best support children's development and learning and (2) to promote policies that support children with special needs and their families. The DEC is one of 17 divisions of the Council for Exceptional Children (CEC), an organization focused on improving educational outcomes for students who have disabilities and/or are gifted. This entry describes the organization's goals, strategies, and major accomplishments as well as outlining its history.

Major Purposes and Goals

DEC and its members are committed to providing high-quality early intervention and education to young children with special needs and their families. To meet this commitment, the organization works in these areas: It advocates for laws and policies that support quality early intervention/early childhood special education; disseminates up-to-date research-based information on quality services and supports; develops standards and positions to guide the field; and publishes "Recommended Practices," a set of practices designed to link research with practice for professionals and families.

Advocacy

DEC maintains a governmental relations position and committee. DEC was a strong voice for the passage of Public Law (PL) 99-457, known as the Education of the Handicapped Amendments of 1986. The prior special education law, PL 94-142, known as the Education for All Handicapped Children Act, did not require services for children with disabilities younger than school age. Yet, the growing body of research, much of it done by DEC members, provided evidence to support the following contentions: that early intervention enhances children's development, enhances families' capacity to support their children, helps children and families be more successful in their communities, and reduces the cost of later special education and

special services. Many of the recommendations made by DEC and its partner organizations were written into the law, now known as the Individuals with Disabilities Education Act (IDEA). The organization continues to monitor legislation, recommend legislation that is consistent with research and values, and encourage advocacy efforts on the part of DEC members.

Dissemination

DEC shares information with its members and the larger early learning field through an annual conference and professional journals. The conference is held each year in the fall, and features workshops, research presentations, practitioner sessions, and networking opportunities for members to discuss accomplishments as well as issues and concerns.

DEC also publishes the research journal *Journal of Early Intervention*. Published quarterly, the journal features data-based articles on research and practice, policy analyses, research methods, and systematic reviews. *Young Exceptional Children* is a practitioner-oriented quarterly journal with a focus on implementing research-based practices in a variety of early care and education settings. Articles are written in a friendly, useful manner to reach an audience of teachers, child care providers, administrators, and family members. Each year, DEC also publishes an issue of the YEC (Young Exceptional Children) *Monograph Series*. The monograph brings together a set of relevant and accessible research-based articles on a single topic. Recent topics include families, challenging behavior, dual language learners, and assessment.

Position Papers

Periodically, DEC develops and distributes position statements as formal expressions from the organization on topics or issues of concern. Position statements are written by small groups of members and then submitted to the entire membership for review before being approved by the executive board. Some of these position

statements are developed jointly with the National Association for the Education of Young Children (NAEYC).

Perhaps the most widely referenced and used position statement is the one developed jointly by DEC and NAEYC in 2009 on inclusion. This statement went through a rigorous review and evaluation process. It outlines and defines the three key features of inclusion: access, meaningful participation, and system-level supports.

In addition, DEC works collaboratively with the CEC and NAEYC to establish and update standards for teachers and early intervention personnel.

Recommended Practices

Recommended practices are lists of practices that are generated by appraising the best available research evidence, gathering consensus views about professional knowledge, and verifying the practices through field validation. In 1991, a group of DEC members recognized that the field did not have a set of practices to guide teachers and other professionals in providing high-quality services and supports. The group embarked on a project to identify the practices using focus group methodology. The first set of practices was published in 1993. The effort was repeated about 10 years later but added an extensive, systematic review of the research literature. This revised set of practices was published in 2000, followed in 2005 by a comprehensive guide that included greater direction for implementing the practices. The most recent set of practices, based on an updated review of the literature, was published on the organization's website in 2014.

History and Major Accomplishments

The CEC, of which DEC is part, is the largest international organization of professionals in the field of special education. CEC works to improve the educational opportunities and quality of life for children and youth with exceptionalities. CEC has a strong role in advocating

governmental policies that support high-quality education for children and youth with disabilities and/or gifts and talents. It sets professional standards for the field and provides professional development. CEC holds an annual conference; publishes journals, newsletters, and position papers; and holds as a major responsibility the dissemination of up-to-date information on educating children with exceptionalities.

In 1964, CEC formed the Preschool and Nursery Committee, and in 1969 CEC held its first topical conference on early childhood. The organization known as DEC was founded in 1973. The first newsletter was published the following year, and DEC's journal, originally called the *Journal of the Division for Early Childhood*, was launched in 1979. In 1980, DEC joined with the Office of Special Education Programs, U.S. Department of Education, to sponsor the annual Handicapped Children's Early Education Program (HCEEP) conference. This federal effort funded demonstration projects that were designed to develop and disseminate effective intervention approaches for young children and their families. HCEEP, in many ways, helped give rise to the field of early intervention/early childhood special education; it provided the need and opportunity for professionals to work together and thus became the springboard for the creation of DEC. The work of these projects, as well as the advocacy of the organization, contributed to the passage of PL 99-457.

DEC held its first conference in 1985. At the annual conference the following year, members celebrated the passage of PL 99-457. This law required states to provide a free and appropriate education for preschool-age children with disabilities and developmental delays and provided incentives for states to serve infants and toddlers. Currently, all states provide services and supports for children from birth onward, guided by the federal law and the practices recommended by DEC.

DEC is an active membership organization. It counts as its most significant accomplishments the advocacy efforts that led to the passage of PL 99-457, the ongoing identification and dissemination of "Recommended Practices," and its service

as the voice for young children with disabilities and other special needs, their families, and those who work on their behalf.

DOCUMENTATION

For an educator, there is nothing more gratifying than seeing one's impact on learning. To be completely in sync with a learner, and responsive to his or her learning in the context of the classroom community, is the pinnacle of good teaching. Given there are many avenues to assessing the art of teaching and learning, none is more powerful than that of pedagogical documentation. Documentation is typically defined as using documents for authentication, to provide factual support, or to serve as a historical record. Missing from this definition is the essence of development that can be told through documentation, that is, the power of imagery and text in creating context for learning, or pedagogical documentation.

Documentation means many things to many people. Whereas a teacher may use documentation to prove effectiveness, the learner may see it as a way to reflect on his or her learning, a parent as a meaningful bridge between the home and school, an administrator as a way to help create a community of learners, and the public-at-large as a sign that the school deserves support in the financial and political arenas.

Documentation, in the academic sense, refers to describing the process of children's learning through observation, work samples, conversation logs, and children's and/or teacher's reflections. Carolyn Edwards suggests that, to impact learning, this information should be analyzed, interpreted, and shared with others. Although documentation is much more than assessing student learning, it can be one effective tool used in combination with the American educational need for "proof" of teaching and learning. When done in a thoughtful manner and with purpose and audience in mind, documentation adds the qualitative story to the quantitative measures of educational assessment.

Accountability and Standardization

The federal No Child Left Behind Act of 2001 required states and school districts to publicly report data on school performance. Collection and dissemination of standardized data is a key component for policy makers but does not provide a deeper understanding of learners as individuals and the impact of societal factors outside of school control. This age of accountability has forced learners to be neatly categorized by test scores and, in some school systems, teachers ranked by how well they can get the learner to conform to standards. School performance involves more than results on summative tests.

Although many educators will attest that nutrition, health, socioeconomic, and family support contribute to student success, how many are actively implementing meaningful alternative sources of assessing student learning? Somewhere in the battle for education for all, standardization has taken precedence. One way to overcome the

numerical categorization of learners is to document, or provide evidence of, learning as it occurs. In *Making Learning Visible: Children as Individual and Group Learners*, Claudia Giudici and colleagues suggest that using a variety of techniques, from photos and text to video and artifacts, to support learning and make learning visible is just part of the critical work in which educators must engage.

Standardized assessment does not mean standardization of instruction. It is still best practice to use data-driven decision-making practices. Although standardized assessment results can give one point of view on student development and teacher effectiveness, additional documentation is always necessary to put all of the puzzle pieces together. A number should not define a person; pictures, video, work samples, text, and the voices of learners can put the number into context.

Types and Uses of Documentation

Having learners reflect on their own development supports them in moving toward higher level thinking. Paper and pencil testing is not necessarily the best judge of student achievement or teacher effectiveness. However, there is a need for educators to use summative evaluation, or evaluation done at the end of a program for the purpose of decision making. Moving beyond test scores, the documentation of authentic learning and synthesis of information learned are necessary tasks for teachers and students. Engagement in metacognitive events such as reflecting on learning allows teachers to see where they have had impact and where they can improve and allows students to think about their learning. According to Lella Gandini and Judith Kaminski, using documentation to become articulate about learning allows the learner to revel in his or her successes and learn from his or her missteps. The most powerful part of the student-led conversation on learning is the student having ownership of the future of his or her education when the documentation is used by the teacher to plan individualized instruction.

If educators are invested in the idea that learners operate in a complex interaction of systems,

including homes, families, schools, and communities, then documentation allows them to make connections among these systems. This is yet another way to value the gifts each learner brings with him or her to the classroom. By using documentation in both formative ways (to monitor and provide feedback on progress) and summative ways, engaging the learner in the analysis of learning, and aligning standards and student learning outcomes with documented learning, teachers can meet the need for quantitative measures by boards of education while providing contextual support for learning through narrative. Documenting children's learning may be one of the most valuable skills a teacher can learn. When teachers carefully collect, analyze, interpret, and display evidence of learning, they are better able to understand how children learn and to help others recognize learning. Judy Helm, Sallee Beneke, and Kathy Steinhilber support these ways of documenting in their article "Documenting Children's Learning" by saying that regular and consistent documentation of children's work can benefit teachers by helping them see the learning process.

By using this more formative process, a teacher can be inclusive of cultural, gender, and familial representations of learning. The process of supporting summative evaluation with ongoing documentation shows respect for the learner as an individual and an individual who is part of a school, community, and family.

How to Implement Documentation

Whereas it is easy to amass a large quantity of "stuff" during an academic term, or year, it is wise to approach the data collection process with a plan. At first, the idea of collecting, organizing, and writing about artifacts for an entire classroom of children can be daunting. Defining the exact knowledge, skills, or disposition being evaluated makes the process for data collection all the more simple and efficient. There is no reason that a teacher would have to incur expense for documentation. Time is the only cost, and it is well worth the investment.

Documentation can be done in a way that makes sense for each classroom and within the

context of the organization. Teachers can use the materials and resources that are present. File folders of artifacts can be presented to learners who can then write about or orally express their meaning; this explanation can be added to a panel or shared at a conference. A simple daily journal with a few photos and text can capture the learning of one day or one event. A large poster panel can be used to document a journey or project. A video or voice recording of a child describing what he or she has learned through a process or lesson can be shared in a presentation. The avenues for sharing learning are endless and must be created in a way that is meaningful to the event, the learner, the teacher, and the audience.

Documentation is a form of assessment that can include the learner at all phases. Teachers can encourage PreK–12 students to help select items that represent their own learning. They can choose work samples (photos, recordings, etc.) showing a progression of development from beginning to end, from assisted to proficient. For example, samples can be chosen showing early attempts to form a written letter of the alphabet and showing the child's completion of writing his or her name. Whatever the evidence, it can be enriched by adding three elements: student reflections on learning, teacher connections between learning and standards, and teacher reflection on the meaning of the documented learning.

Children of all ages can articulate how they feel about completing a task, what they learned, and what the learning means to them. Capturing the learner voice respects them as partners in the learning process beyond test scores and grades. The affective domains of development, social systems, emotions, and familial issues all impact learning and can be used as lenses through which an educator can assess learning.

Documentation alone can be effective but becomes powerful when supported by a connection to student learning outcomes and standards of learning. Early learning guidelines, grade level expectations, and Common Core State Standards can easily be aligned with and supported by documentation. As mentioned earlier, documentation makes learning visible; it provides a visual display

of learner prowess and teacher effectiveness in a contextually supportive format. It is critical that teachers show the connection to standards and learning outcomes to validate the abilities of all children to learn as well as the teachers' ability to teach.

Teacher reflection provides the final analysis of learning. This process connects the dots for whom ever the audience may be. This is the reason for being selective in the beginning and defining the purpose for the documentation with careful thought. Families will seek different information than a college or administrator. The final teacher reflection should include elements of self-analysis on teaching strategies in addition to learner achievement as individuals and as part of a classroom community.

Impact of Documentation

The overall point of documentation is that although educators can tell passionate stories of learning that can make a person weep with pride and excitement, many times they remain only good stories and are not categorized and quantified as meaningful pieces of data that can be used as supporting evidence for learning. The formative storytelling found in this type of documentation can serve as strong evidence of teacher effectiveness. Fancy and formal or quick notes and photos have impact for teaching and learning. Walking into any school one can see examples of student work in the hallways and on the classroom walls. Samples alone do not say anything about the learning that occurred in the process. It is the responsibility of educators to use documentation as a qualitative measure, to support and explain the quantitative, so that each child is respected for his or her own path of learning.

DUAL LANGUAGE LEARNERS

All young children learn about the meaning and structure of language in the first four years, and children can learn multiple languages in these early years. In early childhood education, dual language learners (DLLs) are young children who learn to speak more than one language before the age of 5, for example, learning to speak both English and Spanish. This entry describes who DLLs are, the advantages and challenges faced by DLLs, the process of early language development, and known supports for DLLs' development.

Characteristics of Dual Language Learners

In the United States, more than 15% of children grow up in homes where a language other than English is spoken. The majority of DLLs in the United States live in Spanish-speaking homes in the West and South, but DLLs can be found in every state, particularly near large cities. Compared with children who only learn English, DLLs are more likely to live in two-parent homes and have more siblings. They are less likely to live with a mother who reports symptoms of depression. However, they are also more likely to have risk factors that may threaten development. They often live in homes with fewer economic advantages: low income, parents with only a high school education or less, and one or more parents who are immigrants with limited social supports. Their families may be isolated because of cultural and linguistic differences.

Advantages of Bilingualism

Learning two languages early in life offers cognitive and social advantages to children. Children who learn two or more languages are able to be more flexible in their thinking. Usually, they can consider and weigh different options more easily than monolingual children learning only one language. Bilingual research with older children and adults indicates that they have stronger memory functions, greater ability to selectively attend to stimuli, and greater metalinguistic awareness—that is, the ability to think about how words convey meaning. Ágnes Melinda Kovács and Jacques Mehler found that children growing up bilingual showed cognitive advantages as early as 7 months old, with evidence that DLLs could exhibit a learned visual response when a reward changed more easily than monolingual infants. Knowledge of multiple languages allows children to interact with people from different cultural backgrounds and can aid greater understanding of the world and more economic opportunities later in life. Some research also suggests that being fluent in more than one language may help to protect against dementia in old age.

Challenges for Dual Language Learners

In the first five years of life, DLLs typically develop vocabulary in a single language at a slower rate than their monolingual peers. However, when you combine the words that they know in two languages, the number of words that they know is higher than that of their monolingual peers. This holds true even when you look at low-income samples of children, such as children served in Head Start.

DLLs who have socioeconomic risk factors face challenges and show delays in development that are similar to English monolingual children who experience socioeconomic risks. Delays are evident not just in language development but also in cognitive and mathematics development. Parents with more limited education are less likely to understand child development or to offer the experiences and interactions that will support children's learning.

Language is integral to learning about the world and developing skills needed for success in school. Although some school readiness skills can develop independent of any language (e.g., fine motor skills that help a child to cut and copy figures or letters), most readiness skills depend on language. Children learn concepts and gain knowledge from interactions with others about their experiences and the world beyond their immediate experiences. When children are in environments with adults who do not speak the same language as they do, they often have fewer opportunities to interact with adults and attach meaning to their experiences.

In the United States, acquisition of English is important for later success in schools. Most or all classroom instruction is in English. Fourth graders who are still receiving English as a second language (ESL) services because of their limited knowledge of English are much less likely to demonstrate even the basic level of proficiency in reading and math compared with their English proficient peers. Less than one third of these English language learners (ELLs) attain a basic reading level, and they are much more likely to drop out of school before finishing.

Language Development of Dual Language Learners

Most language development occurs in the first four years of life when the majority of brain development occurs. Children develop neural pathways based on the experiences that they have; therefore, it is much easier for very young children to learn languages than it will be later in life. In the first six to twelve months of life, children learn to perceive the sounds of languages and to produce sounds and communicate with the significant adults in their lives. After the first year, it becomes more difficult to perceive sounds that differ from their first language. Infants learning two or more languages at the same time, or simultaneous language learners, become fluent speakers if they continue to have interaction with others in those languages. Some DLLs are sequential language learners, learning a second language after they have already begun to learn the first language.

The window of opportunity for learning language remains open throughout the early years of life. Overall, the younger a child begins to learn a language, the greater the language proficiency the child can attain. The key to all language learning is interaction with competent speakers of the language. Just listening to the language is not sufficient for learning. Two types of experiences offer children the best opportunity to become fluent in language: (1) hearing a language spoken to them by a native language speaker in the first year of life, and (2) interaction in the language with a competent speaker in the first four years of life. The quantity and quality of the language exposure determine how well a child learns language, whether it is the first language or a second or third.

Currently available research suggests that children develop knowledge of multiple languages in the same way that children learn a first language, although a little more slowly. They learn vocabulary, say single words and then combine words, learn the endings and prefixes that are meaningful in a language (such as how to make words plural), and learn about the structure of phrases and sentences. The order in which they learn the structure and rules of the language is similar to the order in

which children learning only a single language learn those rules.

When young children are sequential learners and begin learning the second language after about 3 or 4 years of age, they go through a series of four stages in learning the second language. In the first stage, a child attempts to communicate using his or her first language. When that is unsuccessful, many scholars contend that most children enter a second stage referred to as a silent stage. The child spends time observing and listening to others communicate. In the third stage, the child begins trying out some words and common phrases and formulaic sentences, such as “I want” and “It is.” In the fourth stage, the child combines words and phrases using the new language to communicate meaning across a range of ideas.

A 2014 review of the research by Theresa Roberts casts some doubt on the existence of the silent stage. The studies used to define the stages were based on small samples that were not representative of the diversity found among DLLs. In addition, the period of observation and silence was usually less than 3 months. As with all young children, teachers need to continue to interact with DLLs as they learn language even if the child is more reticent to speak.

Support for Dual Language Learners

Across multiple studies using varied research approaches (including experimental and descriptive research), DLLs benefit from early childhood education in both home-based and center-based approaches as much as or more than their peers. The age of entry may make a difference. Some research indicates that children younger than 4 years of age benefit more than children older than 4 years.

The quality of the early childhood education program matters. Low-quality programs do not support children’s development. Programs need to have moderate to high quality in order for children to benefit. Above the minimum quality threshold, children in programs with higher quality teaching interactions make greater gains. This effect has been noted in classrooms with children who speak

only English and in classrooms composed largely of children who are DLLs.

Development of language and literacy is a large focus in early childhood classrooms, and practices that support the development of vocabulary in a first language also support the development in additional languages. These practices include frequent opportunities to converse; introducing new words in context and repeating them often; using nonverbal language such as pointing to pictures or objects, facial expressions, and gesturing; reading illustrated books frequently; and talking about experiences as they are happening as well as using language to help children to recall recent events and anticipate what will happen in the near future. Predictable routines can help children feel secure and enable them to attend to learning, particularly supporting them in using language to discuss what has and will happen during their daily activities. When children are learning a second language, they may need more visual cues, such as pictures and objects to help them to attach meaning to words.

The trajectory of a child’s development of a language is related to the quantity and quality of the child’s experiences with language. To maintain two languages, children need continued experience in both languages. When children are learning a second language such as English, continued development of the first language helps to support the child’s knowledge of the world and cognitive development, particularly if the first language is used to help children to learn and reason about the world.

Fostering a rich language environment at home is important. Parents are fluent in the child’s first language. They can help the child to learn to use the language in more advanced and complex ways as they have extended conversations about experiences and books that they read.

Children need to continue to learn words for new ideas and concepts. The initial words in a second language may be words for things in the everyday world, such as food, clothing, everyday tools, and activities. Children need the opportunity to learn words beyond everyday events so that they do not fall behind other children in language and cognitive development. Caregivers, both teachers

and parents, support children by sharing books with them, offering new experiences and having conversations about those experiences, and extending what children say.

Evidence-Based Approaches to Support Dual Language Learning

More research is available about how to support ELLs in K–12. Less is known about how to best meet the needs of DLLs from birth to age 5. Research studies about DLLs often have only small samples and have many limitations, such as not representing the diversity found among DLLs and not using research designs to determine that a particular approach or strategy provides stronger support for DLLs than another approach or than everyday practice. Most studies have been descriptive, exploring relationships between instructional approaches or practices and the development of DLLs. Evidence suggests the importance of several practices, however.

Bilingual Approaches

The area with the strongest evidence is the use of bilingual approaches in instruction, although currently available studies examine this mainly with Spanish-speaking DLLs. Multiple studies using experimental designs provide evidence that including at least some instruction in Spanish is beneficial for children: DLLs make similar or greater gains in English assessment of skills and make greater gains in skills in Spanish. Some research indicates that phonological skills (needed for reading and writing) and vocabulary skills transfer from one language to another. Use of the DLL's primary or first language for instruction is associated with higher levels of academic, social, and cognitive development.

Across studies of the use of the primary language, DLLs receive instruction in their primary language for different periods of time and in different sequences and in different ways. Some programs begin with instruction in the child's primary language and transition to English, whereas other programs alternate between instruction in English

and instruction in Spanish, sometimes across days or weeks and sometimes within a day. For example, in one program a story might be read in Spanish in the morning and in English in the afternoon. In another program, instruction might be in Spanish for a week and then change to English. The amount of time devoted to instruction in English versus instruction in the primary language is not well specified across studies. Although less conclusive, currently available research suggests that bilingual programs with longer periods of instruction in the primary language are associated with more positive long-term academic achievement for DLLs.

When DLLs receive instruction in English only, they tend to lose skills or, at best, stop making progress in their primary language. In homes with parents who are not fluent in English, the DLL's loss of the home language can lead to potentially serious negative consequences by threatening the development of protective factors such as the relationship with the parents, communication with extended family, and connection to family culture and social support systems.

Curricula and Instructional Practices

Studies involving DLLs have examined a little more than a dozen curricula, but evidence supporting the benefits of any single curriculum over another is limited. Many of these curricula target language and literacy. The level of evidence varies from study to study.

The curricula with stronger evidence of positive findings include some common features that have also been investigated with monolingual English-speaking children and proven beneficial. The features of curricula and instructional practices that benefit children's development of language and literacy in particular include a well-specified instructional approach with activities tied to learning objectives; explicit and intentional vocabulary instruction; explicit and intentional instruction in letter-naming, phonics, and comprehension; and reading and discussing books with children.

Explicit instruction in mathematics has received less attention. Some scholars encourage the use of math word problems based on the child's

experiences; providing additional time for problem solving, cognates, and storytelling to help young DLLs solve math problems; and using the primary language to support mathematics development.

Some additional instructional practices have been investigated in isolation. The use of instructional and visual supports and planned peer interactions can support the language development of DLLs.

Instructional and visual supports are common-sense recommendations and follow the types of supports provided to all toddlers, whether they are learning their first language or two languages. Strategies supporting language include providing context with gestures or pictures, pointing, holding up objects, emphasizing key words for meaning, and allowing the child time to process what was said before expecting a response. Without some context for developing language, any learner would have a difficult time.

Positive Peer Interactions

Several studies examine the roles of other children in supporting dual language learning. Available research indicates that providing structured and well-planned paired and small group opportunities for DLLs to interact and practice language with peers who have more developed English abilities supports the English language development and social inclusion of DLLs. Monolingual English-speaking children may be taught strategies for engaging and interacting with DLLs who have limited English. Well-planned peer interactions also support development in other areas as children easily model and imitate one another. Teachers may also provide opportunities for DLLs to focus on literacy content in homogeneous, small group settings to support literacy acquisition.

DUAL LANGUAGE LEARNERS, STRATEGIES FOR

Every young child is in the process of learning a language and learning how language works. This is a mighty task for those young brains as they

make sense of listening and talking, then reading and writing. Some children are learning more than one language at home, at school, or in their community. Early educators need to know how growing up with multiple languages can affect teaching and learning. Early educators must work with each child's individual needs and abilities in both the broad and local cultural context.

Children who enter school speaking a language other than English are often identified as English language learners (ELLs). Early childhood educators debate the use of that term because they realize that all very young children in the United States are still working on learning English—even if that's the only language in their environment. The Office of Head Start originated a different term to describe young children who are still in the process of learning their home language while also learning English: *dual language learners* (DLLs). This term is used most frequently across the field of early childhood education. It is often used interchangeably with ELLs, but it is preferred for young children, especially preschoolers, as a way to recognize that both of their languages need to be supported, honored, and nurtured as they learn.

Young children who come from homes where languages other than English are spoken are the fastest growing segment of the U.S. population. According to the Migration Policy Institute, based on U.S. Census data from 2010 to 2012, these children make up close to 25% of the population of children younger than age 9. Spanish is the most common non-English language, spoken by nearly three fourths of DLLs in early childhood education. However, there are more than 150 other languages spoken in the homes of students throughout the United States.

Even more important to remember is that most teachers of children from birth to age 8 will work with children who come from different language backgrounds. Early childhood teachers are the first to welcome young children into their educational career. They are responsible for the care and teaching of children who may have developmental issues or language issues that have not yet been identified, so every teacher in the early years should be prepared to meet the needs of diverse children.

Some children are learning two or more languages *simultaneously*, as when they have a mother who speaks one language and a father who speaks another. Others are learning two languages *sequentially*—starting with one language and then, when they move to a new country or start a new school, they learn a new language. In either case, children who receive adequate support of both languages will become bilingual. Many early childhood education programs include some activities that expose students to some words and phrases in a new language. Occasional language classes can be an effective way to broaden young children's understanding of linguistic and cultural diversity, but they will not be sufficient to result in true bilingualism. Although there are many definitions of the term *bilingual*, most agree that it refers to a person of any age who can understand and speak fluently in two languages. The two languages do not have to be used equally for the person to be considered bilingual.

First and Second Language Development

Teachers who have a strong understanding of language development are better prepared to teach young children successfully, to support effective early literacy learning, and to ensure desired learning outcomes for diverse learners. Acquisition of a second language occurs on a similar path as acquisition of a first language, but there are some differences to note. Many writers use abbreviations: L1 for first language and L2 for second language. When learning L1, children progress through predictable stages that have predictable time frames. When learning L2, children may start at any point of their development, and their knowledge, developmental level, and language experience will influence how quickly they progress through the phases of second language development.

An important factor that underlies all of language development is the focus of the child's brain on learning sounds and words in the context of interpersonal interactions and for the purposes of communication. Passive or isolated language exposure has very limited effectiveness. So, for example, young children will learn and retain more words

during responsive play activities with adults than while watching a video or repeating words on flashcards. When children are first exposed to speech in their environment, their brain takes on the monumental task of cataloging and making sense of the many sounds they hear. Producing oral language—babbling and talking—is also a critical component of language and literacy development for all children.

First Language

The following list shows how language develops in children's first language.

- Crying/body language: birth–6 weeks
- Cooing—focus on vowel sounds: 6 weeks–6 months
- Babbling—practicing consonant sounds heard in the talk around them: 6 months
- One-word utterances: 12 months
- Two-word combinations/chunks: 18 months
- Sentences: 24 months
- Advanced use of modifiers, tenses, and complex sentences: 48 months

Second Language

The following list shows how language develops in a person's second language at any age, for varying time periods.

- Continuing use of home language
- Observing and listening—may stop speaking during this period
- Formulaic speech/chunks of combined words
- Informal fluency—also called playground language
- Academic fluency—sufficient to support academic learning in new language

A great deal of language development happens before a child says his or her first word. In both L1 and L2 development, children generally understand more than they can say as receptive language develops faster than expressive language. For this reason, it is important that teachers talk to young children as if they understand more than they show

by the words they use. Children need many opportunities to show what they know and can do through actions and play before their oral language catches up.

Research has shown that DLLs have two separate language systems when they are young. They store knowledge according to the language being used when they learned it. This is one reason why it is so important to continue supporting each child's home language in the early years. Even if they appear to speak English very well, still they will have prior knowledge stored in their brain in their home language. As adults, bilingual people have an easier time retrieving information in one language while thinking or talking in another language, but young children are less likely to be able to make that transfer, so they can learn more effectively if both of their languages are used.

DLLs often have smaller vocabularies than monolinguals in *each* of their languages, but their total vocabulary across all of their languages is likely to be the same as the vocabulary of a monolingual child. The rates at which bilingual children reach some language acquisition milestones may vary from what is observed in monolingual children, but these variations are considered differences rather than delays. There seems to be no evidence that growing up with two languages will cause any meaningful delay. As long as children are experiencing lots of language and literacy activities at home in their home language, their progress is likely to even up with monolingual children and possibly even go ahead. Some recent studies have detected certain cognitive advantages of growing up bilingual. One key point to remember is that support of learning in the home language in early childhood actually serves to improve success in English later on. This is because support of their familiar language helps children keep up the rapid pace of learning concepts while they are also struggling to learn English.

Strategies for Supporting Home Languages

With so much language diversity, it is difficult to match every child with a teacher who speaks his

or her language. When the languages don't match, teachers can find materials and strategies to support home language. Here are some suggestions:

- Invite family members or volunteers to read stories, play games, or accompany children on field trips to discuss things with children in their home languages.
- Provide opportunities for same-language peers to play and learn together.
- Obtain bilingual children's books for the classroom. It is not a good idea to read to children in both languages, switching back and from one language to the other in the same sitting. The story can be read at different times in the different languages to help the children focus on just one language during the story. Bilingual stories can be very helpful learning tools for adults because the familiar story and child-oriented vocabulary provide directly applicable language.
- Use bilingual apps, software, games, and videos to help the children make connections between L1 and L2.

Program Formats

A major challenge faced by early childhood educators, as linguistic diversity keeps growing, is finding a balance between what they read in the research, what their curriculum says, and the education regulations of their state. Whereas researchers advocate for significant support of each child's home language in school to help children gain the advantages of growing up bilingual, many states and local school districts focus entirely on the learning of English.

In most states, preschool programs are not expected to comply with regulations that govern K–12 bilingual education or English as a second language (ESL) programs. Illinois was the first state to address prekindergarten in its regulations directly. Others have begun to follow suit. Teachers must familiarize themselves with the regulations and guidelines in their state. Most states are using the WIDA English Language Development standards to guide their programs for English

learners—and many of them have adopted WIDA's Early Language Development standards in English and/or Spanish that are specifically designed to inform and support language teaching and learning for preschool DLLs.

Many language immersion preschool programs, summer camps, or after-school programs are appearing across the country as a growing number of families seek out opportunities to give their young children the gift of learning an additional language. Many private programs and public schools are also implementing dual language immersion formats in which half the children in a class speak one language and the other half speak one other language. This two-language group is taught at alternating schedules in either one language or the other so all of the children are learning each other's language. For example, they may use English on the odd number days and Spanish on the even number days. In dual language immersion, each group of children has to spend some time meeting the challenge of learning content in a new language. This type of program has been found to be quite effective in fostering bilingual development for both language groups and for supporting academic learning as well.

Preschool programs have more flexibility to try different kinds of programs and supports for English learners, but K–3 early childhood educators have to follow district policy and state regulations that determine how ELLs are to be identified, what kinds of classes can be offered, and what qualifications are required for the teachers. Here are some of the options for K–3 supports for English learners:

Bilingual Education

Bilingual education provides content learning in two languages. It can be taught in several ways. Dual language immersion teaches content in two languages to a mix of students, some of whom speak one of the languages and some who speak the other. Additive bilingual, maintenance bilingual, developmental bilingual, or language immersion programs are designed to maintain the child's home language and add a new language for learning.

Subtractive bilingual and transitional bilingual programs are designed to provide some support to both languages, gradually diminishing one language to move the students toward using English.

English as a Second Language (ESL)

ESL supports students of any language background to help them learn English. These supports may be provided as a full class, or the students may be in a general education class with added supports.

English Language Development

English language development offers some support to ELLs in programs that do not offer official ESL classes or bilingual education classes.

Although some preschool programs may adopt models similar to the ones used by grades K–3, they are not usually required to do so. Infant/toddler programs also need to adapt strategies to support diverse home languages in their programs. All programs that serve children birth through age 8 have to consider many factors when deciding on the models and strategies they will use to teach young ELLs/DLLs. These factors can be addressed in a school-wide language plan.

Creating a Language Plan

A language plan can be a formal or informal outline for how a district, a building, or a classroom will adapt to meet the needs of children who are ELLs. It will take into account what languages are spoken by the families, how many children are likely to need services, what languages are spoken by staff, and how to plan for the best match between student language needs and the resources available to meet those needs. The curriculum and the availability of language-appropriate resources must also be considered.

For a school district, the language plan contains details such as screening and assessment protocol, the number of ESL and/or bilingual education teachers to be hired, the location of the classrooms where ELLs will be served, and the resources needed. The building principal or early childhood program director should also create a language

plan to support their leadership and vision for the entire school community and to describe how they will supervise and support the work of diverse staff and engage with diverse families. A classroom teacher needs a language plan to articulate how the needs of each student will be met within his or her daily lesson plans and the parameters of the curriculum. He or she also needs to list the materials and supports needed to meet those needs. Language plans should include strategies for teacher collaboration and for working effectively with families.

Language plans cover policies and procedures, but they can also establish a position on how linguistic and cultural diversity will be treated in the school environment by all staff and families. Professional development can then be arranged to support the elements of the plan as it will become a clear, shared focus for the entire school community.

Identifying ELLs/DLLs

There are three main components to the process of identifying which students are to be considered ELLs or DLLs. Federal guidelines and many states require multiple measures to be used when making placement decisions for students.

A home language survey asks families about what languages are spoken at home with the child. Written surveys should be followed up with personal contact. Because all children younger than age 5 who come from different home languages need support for those languages, additional screening is not usually needed. As children enter kindergarten, the home language survey may be used to determine which children need additional screening to determine placement.

A screening tool or language proficiency assessment is usually recommended for students who are entering kindergarten or the elementary grades. Purchased assessments are meant to be used only in the language(s) in which they were validated. If the assessments are not available in the languages needed, translations will be used as the only alternative. The best practice is to assess a student's proficiency in all of his or her languages.

Teacher observations and parent interviews about the child's understanding and use of any and all languages are very informative in the screening process. For young children, particularly children younger than age 5, the portfolio approach is the most accurate way to assess their language progress and needs.

The screening process that is normally used to determine if a child needs further evaluation for a learning disability would have to be performed in both of the child's languages in order to be accurate. Because so few tests are available in different languages, districts may hire an interpreter or invite a family member to assist. In general, a child who has special needs will show signs of his or her disability or delay in both languages. If the child can only be assessed in one language, it is not possible to tell if the results reveal a pervasive delay or if the child just happens to be less fluent in the language of the test. ELLs who qualify for special education services are also entitled to the same English language development, ESL, or bilingual education services offered to typical students.

Preservice and In-Service Professional Development

Preparing teachers to provide highly effective early education for ELLs/DLLs starts with highly effective teacher education programs. Model college programs have innovative components such as collaborations between early childhood education, ESL, and special education departments that prepare teachers for the diverse students they will encounter. What should teachers know and be able to do?

Cultural Competence. To be responsive to each child's needs, strengths, and interests, it is important that early childhood educators be prepared to understand cultural differences and characteristics.

First and Second Language Development. This is a critical component of every teacher's work and must not be overlooked. When teachers do not

have strong background in language development, they have a hard time understanding the process of literacy development and language learning needs.

Planning the Environment: Effective environments for ELLs have culturally and linguistically appropriate displays, lots of books and materials in the languages of the classroom, and visual supports to aid communication.

Collaborating With Other Professionals: Many teachers report that they need to collaborate closely with specialists who come into their classrooms to provide supports for students who are ELLs and/or have delays or disabilities, or they are assigned to a team teaching relationship. Effective teaching collaboration requires a set of skills that should be learned as part of the teacher education program.

Teaching Strategies: In addition to the background information needed to inform teacher candidates about the field, specific guidance about evidence-based teaching practices for ELLs should also be covered in college programs. Based on the research, some key strategies include

- reading, singing to, and playing with children using their home languages;
- planning lessons and activities that share vocabulary words to give students multiple opportunities to learn and practice new words in different contexts;
- providing lots of visual supports such as pictures, props, graphic organizers, and videos;
- explaining connections between words in L1 and new words in L2;
- giving children plenty of opportunities to have conversations with adults and peers so they can practice their home language and their new language in meaningful interactions using oral expression;
- making sure that language materials and supports are meaningful and useful for learning and communicating; for example, instead of teaching a "days of the week" song that provides no real understanding, teachers can use a song

that helps children remember and understand the difference between inanimate objects and living things; and

- reducing the time spent in large group activities and focusing more on small groups and individual interactions, especially for the birth through prekindergarten groups.

All of these considerations should also be taken into account when planning professional development for practicing teachers and staff. It may be difficult to find time for workshops on each topic needed by teachers of ELLs, but professional development providers who are working with a program on any topic can be asked to include strategies for adapting their ideas for linguistically diverse groups.

Similarly, when purchasing a new curriculum, teachers and administrators need to ask how that curriculum can be used effectively with ELLs/DLLs. There are many software solutions and apps available to teach and support language development. Technology can be very helpful to enhance teaching supports for ELLs/DLLs with anything from searching for appropriate songs, to making learning prompts with digital photographs, to downloading sophisticated learning apps and software. Care must be taken to ensure that choices are developmentally appropriate and that they are not used for rote memorization or passive listening. Active engagement with language learning and opportunities to use the language in meaningful ways must be the focus.

Parent and Community Involvement

Highly effective early childhood education for ELLs/DLLs at any age depends on the program's ability to connect with each child's language and the culture that is relevant to that individual. The best resources for these purposes are the child's own family members. They have assets to contribute to what happens in school. They also have time with the child when he or she is not in school to further extend and enhance learning in the home language and in English. Engaging with parents as true partners in the child's education by giving

them home literacy skills and resources and by showing them that their help is needed at school goes a long way toward ensuring a child's success.

Community volunteers can also bring language and cultural assets to the program, so effective outreach is an important part of a highly effective program. Communication is key. Messages intended for linguistically diverse staff, students, families, and the community at large often can be improved by reducing the number of printed words. With shorter messages, newsletters, and policy documents, schools have a much better chance of connecting with readers. Skilled translators are more accurate than online translation programs. Simple sentences and lots of images help ensure important information is understood. Seeking feedback from staff, families, and volunteers can improve handouts, notices, posters, and important documents and strengthen the entire school community.

Conclusion

As the field of early childhood education grows and changes in response to the rapidly changing population of the United States, there are many factors to consider. Educators at all levels have to learn more, change their practices, and stay informed about changes in regulations, research, and recommended practice. This means that college professors, curriculum developers, authors, organizations, professional development providers, software designers, toy manufacturers, social service agencies, and libraries all have to rise to the task because they all contribute to the success of every teacher. The number of DLLs will continue to grow for the foreseeable future, and the work of highly effective early childhood educators who are prepared for this diverse population can help to ensure the success of the whole education system.

DUAL LANGUAGE LEARNERS AND CRITICAL THINKING STRATEGIES

The United States has a large population of children who are learning two languages, sometimes known as dual language learners (DLLs). The use of this term indicates that English is not the only language a young child is learning; rather, it is assumed that a child is emerging bilingually. However, school districts often use the term *English language learners* (ELLs) and the federal government also uses *limited English proficient students* (LEPs) as a descriptor for children enrolled in elementary or secondary education from 3 to 21 years of age who speak a home language other than English and have yet to sufficiently master English in order to meet standards and excel. The term *emergent bilinguals* honors the complexity of children's language development and recognizes that they are developing their home language(s) and literacies in English if supported in their learning environments. Emergent bilingualism indexes an understanding of the complexity of children's language development, which is dynamic and exists on a continuum.

Demographics

The federal government identifies ELLs using census data and state-reported data. There are inconsistencies in state reporting, and the American Community Survey, produced by the U.S. Census Bureau, is based on estimates that present a margin of error, particularly in under-reporting young children not yet enrolled in school because census data are used for identifying students ages 5 to 17 for distribution of funds.

Census data show that about one out of five children in the United States is growing up in a household where a language other than English is spoken. In addition, the majority of ELLs are being educated in urban poor areas (De Cohen & Chu Clewell, 2007). Using free and reduced lunch numbers to ascertain socioeconomic status, Clemencia De Cohen and Beatriz Chu Clewell found that the incidence of poverty is significant, at 72% in elementary schools with concentrations of ELLs. Across the United States nearly 70% of all ELL children are enrolled in 10% of elementary schools in metropolitan areas (Cosentino de Cohen, Deterding, & Clewell, 2005). Patricia Gándara and Gary Orfield (2010) reported that ELLs attend the most impoverished schools, which related to their isolation in segregated schools. Further, Russell Rumberger and Loan Tran (2010) concluded that the factor that affects the achievement of English language learners is the degree to which they were segregated. Many sources report an exponential growth of people speaking languages other than English, from 23 million in 1980 to 60 million in 2014 (Callahan & Gándara, 2014). According to the National Center for Education Statistics, ELLs made up 9.2% total student enrollment in 2012–2013. This significant student population encompasses more than those receiving services, for, as Ofelia García points out, the ELLs are “only the tail of the elephant” of millions of bilingual and multilingual children. The potential of the DLLs in the United States can be seen as a resource in an increasingly global and multilingual world.

Critical Thinking and Dual Language Learners

Critical thinking in early childhood goes hand in hand with oral language development. That is, it is through language and communication that children develop the intellectual dispositions to explore new ideas (Genishi & Dyson 2009). Dual language children have the additive benefit of being able to understand and express their ideas in more than one language. Therefore, we work from the principle that bilingualism is a resource (Ruíz, 1984) and see orientations toward critical thinking and inquiry classrooms as aligning with ones that view bilingualism as a social, intellectual, and global asset.

Research

Contact with more than one language is commonplace in many parts of the world, and there are various societal benefits associated with speaking more than one language fluently. With that said, there is a great deal of confusion and several myths that surround the topic of bilingualism and early childhood education (García, 2009). As a result, research that supports critical thinking and DLLs places particular emphasis on tapping into a child’s linguistic and cultural knowledge. In addition, acquiring more than one language does not equate to a deficit. Rather, research points to the need for rich learning opportunities in more than one language. Such practices best support critical thinking when they occur in an inquiry-based classroom with ample opportunities to engage with peers and explore new content and materials.

Tapping into the children’s *funds of knowledge*—the accumulation of a child’s cultural, linguistic, and historic background knowledge (González, Moll, & Amanti 2005)—can uncover new ways to promote critical thinking and inquiry among child DLLs. Celia Genishi and Anne Haas Dyson describe children’s linguistic lives and social worlds as inherently complex and diverse, and they locate learning within a diverse array of language-mediated events. Additionally, a major principle of dual language learning is that language knowledge transfers: “If a child learns how to read

in one language, that child knows how to read, and that general ability will facilitate learning to read in another language” (Krashen, 1996, p. 23).

Whenever possible, home language(s) should be used in educational programs for DLLs, in bilingual programs that use it as a medium of instruction, or to ensure comprehension or to scaffold instruction in English, as in the Sheltered Instruction Observation Protocol (SIOP) model. Typically, the number of students of the same language group that are in the community, or the ability to provide appropriate teachers and curricula, determines the model of programs for DLLs from different language backgrounds. Research consistently shows that programs that provide extended instruction in a home language—such as dual language programs—outperform programs that offer short-term instruction in home languages, as in transitional bilingual education, and that bilingual proficiency and biliteracy positively relate to academic achievement in both languages (Genesee, Lindholm-Leary, Saunders, & Christian, 2006). Teachers honor and support the development of children’s home languages, even when they do not speak them, by utilizing resources such as print, books, audiotapes, and other resources such as parents and community members (Schwarzer, 2007).

Practice

Emergent bilingual children need quality educational opportunities to build on their background knowledge and to socially construct their learning through tools (Vygotsky, 1978) such as oral language (Fassler, 2003), instructional conversation in reciprocal dialogue, cooperative learning (Kagan, 1986), and diverse entry points into curricula that draw on their interests and their semiotic, linguistic, and cultural assets (Siegel, 2006). In classrooms with linguistically diverse children, teachers engage children in critical thought to promote deep disciplinary knowledge through open-ended questions, provide materials and environments that provoke expression, and nurture intellectual discovery. Young children participate in learning through projects and activities that hold them to high

expectations for their competencies by responding to their strengths and needs to enrich their experiences. Effective classroom teachers scaffold challenging subject-matter content by using concrete strategies for explanation and clarification of concepts around language and literacy practices. Critical thinking may be modeled in discussion around texts and language, where children make meaning. Additionally, metalinguistic knowledge might be leveraged to discuss language structures and patterns, so students may draw on their knowledge of multiple languages to comprehend new academic vocabulary.

DUAL LANGUAGE LEARNERS AND THE DEVELOPMENT OF SELF-REGULATION

In the United States, educational practices in many schools focus on high-stakes testing and accountability without regarding core skills such as self-regulation. Equating the results of standardized test scores with actual learning without considering or measuring for other critical skills in a child is misleading. Self-regulation is a skill used as a predictor of school success rather than academic content itself. Measuring self-regulation in dual language learners (DLLs) is a challenge because DLLs enter preschools with lower expressive and receptive language skills that are necessary to learn regulatory skills. Specifically, they lack the language to socially interact with adults and peers in the classroom setting; thus, they are unable to learn socially acceptable behaviors and emotions from classmates and teachers. This leads to the lack of skills required to regulate typical behaviors and emotions, which then would allow them to acquire cognitive regulation. In order to learn, a child's behavior and emotions need to be regulated first.

Concurrently, the implementation of the Common Core State Prekindergarten Foundations linked to the Common Core State Standards suggests that preschools should adhere to higher level standards for literacy/language arts, science, history, and mathematics in order to better prepare

them for later grades. Yet, research demonstrates that students who enter kindergarten without self-regulatory skills, specifically DLL students, are at greater risk for difficulties such as lower levels of academic achievement.

Self-Regulation

Self-regulation “is a deep, internal mechanism that enables children as well as adults to engage in mindful, intentional, and thoughtful behaviors” (Bodrova & Leong, 2008, p. 56). Self-regulation has also been defined as having two major factors. One is the capacity to monitor inhibitory aspects. The second factor is working memory, the ability of a child to hold, update, and manipulate verbal and nonverbal information, also referred to as cognitive regulation. Self-regulatory skills represent an important developmental factor in young children as these skills allow them control over their thoughts, feelings, and behavior.

Dual Language Learners

The steady increase in students with limited language has been of growing concern. Dual language learners are those students who are younger than age 5 and are learning two languages simultaneously. Hence, they lack full proficiency in one language, not allowing them to use one language to support the acquisition of the other language. According to the U.S. Census Bureau, there was an increase of about 152% from 1980 to 2010 of children who spoke a language other than English at home in the United States. The growth of the bilingual population poses the issue of how to properly address linguistic and self-regulatory skills in schools. Yet, despite the increase, there still remains a paucity in the body of literature that discusses the development of self-regulatory skills in DLLs.

Methods

As there appears to be a paucity in the literature of self-regulation and DLL preschool students, research was conducted to examine the connection between

self-regulation in DLL preschoolers and academics. The research was conducted in the school year of 2012–2013 with children who attended one Head Start and one universal prekindergarten (UPK) setting. The UPK setting in particular had a school–university partnership with Long Island University Post at the time of data collection. The following hypothesis was examined: It is predicted that there will be a positive relationship between self-regulation and language acquisition skills of DLLs, such that as self-regulation increases, language skills will also increase.

Participants

A sample of 70 students participated in this study from two different settings. The mean age for both settings at Time 1 was 4.5 and at Time 2 was 4.9 years old. The ethnic composition sample was 56% Hispanic/Latino, 43% African American, and 1% White. Thirty-two students were categorized as DLLs. DLL classification was based on surveys filled out by parents or guardians during enrollment and teachers’ evaluation of the students’ language level.

Setting

Data were collected from two preschool settings. The first setting was a state-funded UPK program in a low-income, ethnically diverse district. The second school was a federally funded Head Start program. The Head Start was located in the same ethnically diverse community as the UPK program.

Instrumentation

Standardized assessments were used to collect data in Time 1 and Time 2. These sets of scores were analyzed and compared to measure the relationship between self-regulation and academics.

Preschool Self-Regulation Assessment (PSRA)

The Preschool Self-Regulation Assessment (PSRA) is a battery of self-regulatory tasks. The

tasks were used to assess children's (1) impulse control and (2) cognitive control.

Emergent Literacy Measures

The Get Ready to Read (GRTR) and Expressive/Receptive One Word Picture Vocabulary English/Spanish (EOWPVT-4) instruments were used to measure emergent literacy skills.

Language Measures

To better account for language, the Pre-Idea Proficiency Test (Pre-IPT) and expressive and receptive vocabulary skills were used. The Pre-IPT measured for proficiency in print and phonological skills.

Results

Hypothesis 1 examined the relationship between self-regulation skills and language acquisition skills in DLLs. Two Pearson r correlations were used to measure the association between the academics and self-regulation variables. A Bonferroni adjustment was calculated to control for Type I error inflation; thus, significance in this hypothesis is considered at $\alpha = .025$ ($.05/2$). Finally, a one-tailed correlation was conducted.

Time 1 correlation revealed a significant positive correlation ($r = .528, p < .01$) between cognitive control and language with a moderately high association. Thus, 28% of variance in cognitive scores can explain for language proficiency. Time 2 results revealed cognitive control and language had a significant positive correlation ($r = .687, p < .01$) with stronger association (47% of variance in cognitive scores can explain for language proficiency). For Time 2, cognitive control was statistically correlated with vocabulary ($r = .589, p < .01$) with the strength of the correlation moderately stronger than Time 1. Thus, 35% of students' cognitive control can explain vocabulary skills. These findings indicate that the ability for cognitive control (a form of self-regulation) can be explained by the gains made in vocabulary skills.

Discussion

DLLs showed gains in language and cognitive control for Time 2 (oral proficiency ($r = .687, p < .01$) and vocabulary ($r = .589, p < .01$). Eighty-two percent of the variance in language could be attributed to cognitive control. The interpretation of this finding is derived from the concept that "language leads to consciousness, but then it is the conscious use of language in self-directed speech that allows children to exercise control over thoughts, actions, and emotions" (Muller, Jacques, Brocki, & Zelaso, 2009, p. 57).

Schools need to provide a strong language program that is sensitive to the needs of DLLs and their language needs. Lev Vygotsky's theories on speech and language suggest that self-regulation of thoughts and behaviors is acquired through the internalization of children's teacher or caregiver's speech. The positive correlation results showed that language is a factor in the development of cognitive self-regulation, which later impacts academic achievement. Supporting language and socialization in DLLs allows for communication leading to greater opportunities in learning. This development of language skills serves as a foundation of early reading skills, as these skills require that a child be phonologically aware of sound segments within spoken language.

E

EARLY CHILDHOOD EDUCATION

Early childhood education (ECE) is the broad sector of education serving children during the early childhood years, a distinct developmental period spanning birth to age 8. ECE includes educational services provided in a wide range of settings, including child care centers, family child care homes, nursery schools, private preschools, Head Start programs, as well as public elementary schools and after-schools that offer preschool or kindergarten to third-grade programs. The primary purpose of ECE is to promote child development and early learning. This entry defines and describes ECE and its historical roots. Then it examines three key aspects of ECE: curriculum and instruction, children and families, and quality.

Overview of ECE

ECE is a complex sector of education. Whereas most ECE services for children birth to 5 are offered in private or community-based settings, most ECE services for children ages 5 to 8 take place within the public school system. The private or community-based ECE settings include family child care homes, nursery schools, preschools, Head Start and Early Head Start programs, child care centers, and after-school programs. The complexity of the ECE sector is largely due to the fact that services are delivered across such diverse

settings, with varying standards, policies, and service delivery models. Furthermore, ECE also serves multiple purposes, including supporting the healthy development and early learning of young children, and in many cases, also supporting parents' and families' ability to work by providing safe and stable care for their children. In the past, this dual purpose fueled debates about whether certain types of ECE were intended to provide child care services versus educational services. Increasingly, high-quality ECE is defined as both education and care. Research has shown that young children need safe, stable, educationally stimulating, and caring environments and relationships in order to learn and to thrive.

The ECE field is undergoing dramatic changes now, with heightened standards for professional preparation, growing research evidence about best practices, and an increased federal role in early education policy. The ECE sector has experienced rapid growth over the last decade with steadily increasing enrollments of children. Several forces have driven this growth. First, research has documented the significant potential for quality ECE to enhance school readiness and prevent the achievement gap. ECE is now widely viewed as important for ensuring that all children, particularly low-income children, enter school ready to learn. ECE is considered the foundation for children's success in school. Second, prominent economists such as Arthur Rolnick and James Heckman have publicly highlighted the return on investment of ECE. For

each dollar spent on early education, according to various studies, society gains back an estimated \$8 to \$15 in funds that would have otherwise gone to remedial education and social and economic supports later in life. Third, most parents of young children now work, and therefore there is a greater demand for ECE services.

Unlike many other wealthy countries, the United States does not offer universal access to ECE. The compulsory public education system in the U.S. begins at kindergarten and first grade, which ensures universal access for children beginning at age 5 or 6. ECE for children birth to 5 is primarily the responsibility of individual families, who must find and pay for ECE services. Limited voluntary public programs and policies provide financial support for some groups of children birth to 5, such as children with special needs, children living in poverty, those exposed to abuse or neglect, and children of low-income working parents.

Historical Influences on ECE Theory

The history of early childhood education in the United States has been strongly influenced by several Western European theorists, including John Amos Comenius, Johann Pestalozzi, Friedrich Froebel, and Maria Montessori.

In 1658, Comenius (1592–1670) authored *Orbis Pictus*, the first illustrated textbook for children. This book, along with Comenius's illustrated alphabet book, reflected his beliefs that children's learning should be engaging and driven by their own interests, and that children should be taught in their native language rather than in Latin. Comenius believed that learning should be pleasant rather than punitive; he opposed physical punishment and promoted the idea that children's learning should be active and experience-based.

Like Comenius, Pestalozzi (1746–1827) believed that the best motivator of children's learning is their interest. Pestalozzi took a developmental view of learning, arguing that children master knowledge and skills in various stages. He embraced the "whole child" perspective, emphasizing the integration of children's moral, intellectual, physical, emotional, and social development.

Froebel (1782–1852) founded a school he called a garden for children, and today he is known as "the father of the kindergarten." Froebel believed that children's development occurs in stages, and that teachers must observe children's actions in order to understand how this development occurs. According to Froebel, learning occurs only when the child is ready and cannot be made to fit an artificial timetable. His kindergarten encouraged free play, although in fact this play was semi-structured by the use of Froebel's "occupations" and "gifts"—planned experiences (lacing paper strips, making models) and concrete materials (colored balls, cubes) that engaged children in representative play and learning. Froebel's work resulted in a widespread kindergarten movement in the United States. Teachers who studied his methods implemented them in kindergartens across the country.

Montessori (1870–1952) emphasized the importance of children's environments on their learning. Her theories were rooted in her experiences working with poor children living in Rome; in demonstrating that early education for needy children is less costly than later intervention or remediation, she provided the main justification for early childhood programs like Head Start. Montessori advocated for a sensory approach to learning and designed classroom environments and materials specifically to promote children's learning. Her approach was quite individualistic; she did not believe that social interaction is integral to children's learning and was dismissive of play as a mode of learning. Montessori was an early proponent of the importance of literacy learning from a young age, and her work reflected her belief in a strong connection between learning to write and learning to read.

The Evolution of ECE Practice in the United States

The theories just described contributed to the development of various movements in the progression of American ECE, beginning with the kindergarten movement, rooted in the ideas of Froebel. In 1856, Margarethe Schurz (1832–1876), a German immigrant to the United States who had studied

with Froebel, established a kindergarten for German-speaking children in Wisconsin. Schurz influenced social reformer Elizabeth Peabody (1804–1894), who organized the first English-speaking kindergarten in the United States and wrote the first American kindergarten teacher textbook. Peabody's work in turn inspired Susan Blow (1843–1916), who founded the first public school kindergarten in St. Louis in 1873. Blow became a strong voice in promoting the establishment of kindergartens across the country. Both Peabody and Blow saw teacher training in Froebelian ideals as essential to the movement, and traveled widely to promote these principles. Blow would go on to found the International Kindergarten Union in 1892, which later became the Association for Childhood Education International.

The progressive education movement of the early 20th century had a significant impact on the field of early childhood education. John Dewey (1859–1952) was a leader in this movement, committed to reforming education to make it more democratic. Dewey saw schools as having a responsibility to produce well-rounded citizens ready to function effectively in a democratic society. He believed teachers should work together with children to assist with their learning, rather than act as disciplinarians whom children learn from passively. Likewise, he believed in using an integrated curriculum that utilizes multiple subjects simultaneously to address learning objectives, an approach that is standard in early childhood education today. The progressive education movement encouraged teachers to consider individual differences among their students.

The kindergarten movement eventually expanded to include schools for even younger children, known as nursery schools. The nursery school movement grew out of the work of Patty Smith Hill and Lucy Sprague Mitchell, and paved the way for the broadening of the early childhood education field.

Patty Smith Hill (1868–1946) started her own kindergarten, later developing a new curriculum rooted in a multidisciplinary approach that involved other professionals such as social workers,

psychologists, and physicians. Hill felt that a primary purpose of kindergarten was to build on the learning that takes place at home and to connect home and school in a meaningful way. She wrote poems and books to help children learn to read and developed play materials. Wanting to preserve high standards during a time of rapid growth in nursery schools across the country, Hill spent 30 years on the faculty of Teachers College in New York and was active in the field. In 1926 she founded the National Committee on Nursery Schools, which in the 1960s became the National Association for the Education of Young Children (NAEYC). Today, NAEYC is the largest, most prominent professional association for the ECE field.

Lucy Sprague Mitchell (1878–1967) studied under John Dewey and went on to found the Bureau of Educational Experiments in 1916, a teacher training and research organization. The Bureau was later renamed the Bank Street College of Education, and Mitchell's ideas became known as the Bank Street approach. The approach is rooted in the belief that children's firsthand experiences, such as taking field trips or working on projects, play a large part in broadening their perspective. Like Hill, Mitchell authored many children's books and established a writer's workshop for children's book authors. Her Bank Street approach became a model for the Head Start program.

The early 20th century also saw the rise of parent cooperative nursery schools, or co-ops. Under this model, parents administer the school, hire teachers, and volunteer in the classroom. The co-op movement grew through the mid-20th century, but the number of co-ops declined as more mothers entered the workforce. These same forces influenced the child care movement, which focused on the need to support working parents as well as poor families.

The child care movement was presaged by the work of the McMillan sisters, Margaret (1860–1931) and Rachel (1859–1917), who established day nurseries to serve children living in the London slums. Their program promoted healthy development through outdoor play, nutritious food, and rest. Similar nurseries were established

in the United States by the Works Progress Administration (WPA) during the Great Depression in the 1930s. These centers created jobs for those who worked there and enabled parents with small children to seek work. The WPA nurseries were among the first to serve young children from poor families; however, there was little emphasis on education and many were staffed by teachers with little formal training. During World War II, more women entered the workforce to replace men who had joined the armed services. The Lanham Act funded emergency work-site child care centers to accommodate these women and their families. However, as men returned from the war and women returned home, centers funded by the Lanham Act were closed.

In the later 20th century, the expansion of early childhood education in the United States was driven by the Civil Rights movement of the 1950s and 1960s. As part of President Lyndon Johnson's War on Poverty, the Head Start program was established. Head Start represented a joining between the middle-class nursery school and working-class child care movements. The Head Start philosophy centers on serving the whole child and promotes parent involvement. Head Start programs have served as a laboratory for important research in early childhood education and continue to influence the evolution of the field.

Curriculum and Instruction in ECE Today

A unique aspect of ECE is its emphasis on child development, in addition to education's traditional content areas such as literacy and mathematics. Early childhood education seeks to promote healthy development in all key domains, including physical, social, emotional, cognitive, and language development, as well as approaches to learning. ECE programs serving children birth to 5 have historically emphasized children's development in these domains. The academic discipline-specific content areas include literacy, mathematics, science, social studies, health, and the arts. ECE programs serving children in kindergarten through third grade have historically tended

to emphasize children's learning in these content areas. Increasingly, ECE programs integrate both developmental and content area learning.

The dominant pedagogical approach in ECE is referred to as *developmentally appropriate practice* (DAP). DAP refers to practices that promote optimal learning during the birth to age 8 period. The concept of DAP has its roots in research evidence about how young children learn, and was formally defined and developed by the NAEYC in 1986. Since that time, it has been periodically revised and expanded, most recently in 2009.

The DAP framework guides teachers to make decisions about their teaching based on three key factors: (1) knowledge of child development, (2) knowledge of individual children, and (3) knowledge of children's social and cultural contexts. Considering all three of these factors, teachers make decisions about planning and implementing developmentally and culturally appropriate educational activities and experiences with the specific children they serve.

A range of curricular and philosophical approaches are used in ECE, and many are considered consistent with DAP. These approaches include project-based learning, emergent curriculum, theme-based curriculum, and models such as Montessori, HighScope, and the Reggio Emilia model adapted from Italy. Curriculum in infant-toddler programs is often embedded into natural caregiving routines, such as feeding and diapering. There is no national curriculum for ECE programs. In some cases early educators or school districts develop their own curriculum, and in other cases ECE programs or school districts purchase a published curriculum.

Many ECE programs are designed to be inclusive of children with special needs, and they adhere to the principles of the Individuals with Disabilities Education Act (IDEA), which was first enacted in 1975 and has been reauthorized since then. Inclusive ECE programs often utilize a universal design approach, a flexible approach that takes into consideration differing needs in order to customize and modify teaching to support individual children's learning.

Caring is an important component of ECE. Nel Noddings (1929–) is an educational philosopher known for her contributions to developing the ethic of care in the educational context. The ethic of care guides teachers to make decisions based on the unique individual needs of each child. Rather than applying a one-size-fits-all approach with children, an ethic of care argues for the importance of individualized responsiveness and attentiveness in the context of caring, reciprocal relationships that promote growth. These caring relationships also serve to promote the development of prosocial behavior among children. Current research highlights the central importance of positive and reciprocal teacher–child relationships for achieving educational outcomes.

Play-based learning is another important concept and practice in ECE curriculum and instruction. Developmental science and theory document how children learn through play. This theory and research provide the rationale for play as a method of learning. Through play, young children actively construct knowledge in meaningful ways, through experimentation and social interactions. Jean Piaget's (1896–1980) constructivist learning theories have had a major influence on ECE. His theory explained how children construct knowledge through meaningful experiences. Lev Vygotsky's (1896–1934) sociocultural theory offered another influential perspective. Vygotsky argued that children learn through social interaction and in collaboration with others, highlighting the important role of social play in learning. Research continues to document how young children's play contributes to specific developmental gains across multiple domains such as language, cognitive, and social development.

Early learning standards also guide curriculum and instruction in ECE. The majority of U.S. states have early learning standards that establish a framework for what children at each age or grade level are expected to know and be able to do. Most states have early learning standards starting at the preschool level (and continuing on through 12th grade), and many states have also developed early learning standards that include

the infant and toddler years. Most states have adopted the Common Core State Standards for math and English language arts, which include kindergarten through third-grade standards applicable for these grades within ECE. These learning standards explicate what children should know and be able to do at each level, but they do not mandate a specific curriculum. A wide range of curriculum and assessment approaches can be used to teach within the early learning standards frameworks.

Children and Families

Family support, engagement, and involvement are important components of ECE for three primary reasons. First, ECE programs have an ethical responsibility to engage, support, and partner with families to provide high-quality care and education. Infants and young children are part of, not separate from, their families. To understand and respond to children, ECE teachers must know each family and learn about their routines, culture, and hopes and dreams for their child. Young children and their families are the most racially, ethnically, and linguistically diverse segment of the U.S. population today. Families also vary in their structure or composition, from two-parent families with a mother and father to same-sex families with two mothers or two fathers, and from single-parent families to families headed by a grandparent or a foster parent. Cultural competence, knowledge of families' goals, and an appreciation for family diversity are all essential in ECE.

Second, ECE's clients or "customers" include not only children but also their families. Because families are responsible for finding and paying for most ECE services for children birth to 5, families are customers and ECE programs must respond to the needs and concerns of their customers. This includes the responsibility to support parents' need for safe, stable care during the hours in which parents work or attend school.

Third, parents can be thought of as a child's first teachers. ECE programs can help support and enhance parents' knowledge and skills about child

development and early learning. Strong evidence has shown that parent involvement in early education is associated with improved developmental and educational outcomes for children.

One central challenge families face is gaining access to affordable high-quality ECE. Prior to kindergarten, families are typically responsible for finding and paying for ECE. A national network of child care resource and referral agencies provide parents with assistance searching for quality and affordable ECE services. Yet the cost of ECE is unaffordable for many families, and there are not sufficient public supports available for families to cover these costs. In addition, there is a shortage of high-quality ECE for infants and toddlers. Therefore, some families are not able to access ECE programs for their children until they reach the age of 5 or 6 and enter public school.

To address these gaps in access, some states or cities now offer universal preschool for 4-year-olds. Some federal programs provide support to enable families of younger children to access ECE programs. For example, the federal Head Start and Early Head Start programs provide comprehensive educational and family services for low-income families with young children birth to 5, including children with special needs. The Child Care and Development Fund is another federal program that provides financial assistance in the form of vouchers to help subsidize the cost of child care for low-income parents so they can work or attend school. Neither of these programs is funded at a level sufficient to serve all eligible families, so only a portion of eligible families receive these services.

Quality in ECE

The quality of the ECE workforce and ECE programs is essential for healthy child development, positive early learning outcomes, and young children's long-term success in school and in life. Quality is at the heart of effective ECE. Strengthening the workforce and improving program quality have been, and continue to be, a major focus of professional associations, advocacy groups, and government.

Workforce Quality

Early educators serving children birth to 5 are the most racially, ethnically, and linguistically diverse sector of the education workforce, birth to postsecondary. Supporting a diverse workforce of educators to obtain the appropriate credentials and competencies, and retaining and advancing them in the education workforce, is essential for quality ECE.

Over the last 20 years, there has been a push to professionalize early education. As a field, early childhood educators have less formal education and are paid less than other educators. Even when early educators hold comparable educational levels and credentials, they are paid less on average than educators of older children. There are also inequities in pay between public schools and private child care and preschool programs and Head Start. Early educators working in public schools are paid more on average than early educators working in these other settings. Many are working to professionalize the field of ECE.

A professionalized field is one in which the following four primary elements are present: (1) a professional association, (2) a code of professional ethics, (3) a systematic base of knowledge, and (4) a system of formal qualifications that includes a career ladder. The first three elements are all established in the ECE field, and the fourth has been the focus of recent efforts to advance the field and ECE quality.

NAEYC is the largest and most prominent professional association for the ECE field. Other important national professional associations include ZERO TO THREE, the National Association for Family Child Care, and the National AfterSchool Association. NAEYC produced the first code of ethics in 1989, and it has been revised regularly, with its most recent update completed in 2011. The Code of Ethics specifies the core ideals and principles that guide ethical practice and professional responsibilities to children, families, colleagues, the community, and profession.

The specialized knowledge base about ECE teaching and learning has grown immensely in recent years. A long history of theory and research on early learning, along with new research evidence

about brain development and the science of early learning, inform a solid knowledge base for the field. The final element of a profession, the selection and training and certification of its professionals, has been developed in some respects but this is also an area for future growth and development of the ECE profession.

Professional certification and credentialing pathways specify how a professional enters the field and advances professionally. In ECE, there are different possible entry points. The first formal credential in the field is the Child Development Associate credential administered through the Council for Professional Recognition. Teacher preparation usually takes place at a higher education institution, particularly for educators who teach in public school ECE. Many public and private higher education institutions offer associate's, bachelor's, and master's degrees in ECE, and some offer doctoral degrees in ECE or a related field of study. Public schools and Head Start programs typically require teachers to have a college degree, whereas some community-based child care and preschool settings do not. However, in recent years, there has been a growing push for teachers to earn a college degree, and the NAEYC national standards for accreditation of high-quality ECE programs call for teachers to have a bachelor's degree. NAEYC has a well-established set of Standards for Early Childhood Professional Preparation Programs that specifies what early educators should know in each of the following areas of professional competencies:

1. Promoting child development and learning
2. Building family and community relationships
3. Observing, documenting, and assessing to support young children and families
4. Using developmentally appropriate approaches with children and families
5. Using content knowledge to build meaningful curriculum
6. Becoming a professional

ECE professional development also includes training, coaching, and technical assistance, provided by

a wide array of local and state entities. In the past, professional development typically focused on workshops and group trainings to introduce new knowledge and skills. Based on evidence about how teachers successfully improve their practice, the trend in professional development has now shifted to include coaching. Coaching is an interactive process in which a coach works directly with a teacher to refine, improve, or implement a specific set of practices to achieve a desired outcome.

Professionalization is important to raising the status of the profession and affirming the unique developmental, relational, and pedagogical expertise required for high-quality ECE. However, there have been debates in the field about how to further professionalize in order to most effectively preserve and promote workforce diversity, higher educational standards and professional competencies, and to ensure equitable compensation. For example, one hotly debated question is whether ECE teachers must have a bachelor's degree in order to be considered highly qualified. Another question has been how to create more equitable compensation systems, so that credentialed teachers earn comparable salaries whether they teach preschool in a Head Start program, a public preschool classroom, or a community-based child care center.

ECE Program Quality

Both highly qualified teachers and high-quality ECE programs are needed to support ECE's purpose of promoting healthy child development and early learning. High-quality ECE programs provide safe, nurturing, and educationally engaging environments and relationships for young children. High-quality programs have the following characteristics: a high ratio of teachers to children, small group or class sizes, developmentally appropriate curriculum and assessment, consistent daily routines, a safe and healthy environment, engagement with families and the community, and strong leadership and management practices. The quality of an ECE program is usually assessed through observational methods and can include structural quality elements such as the number of children's books available in classrooms as well as process

quality elements such as whether teachers regularly engage children in back-and-forth conversations. Prominent measures of ECE quality include the Early Childhood Environmental Rating Scale (ECERS) and the Classroom Assessment Scoring System (CLASS). NAEYC administers a system for national accreditation of high-quality ECE programs, based on a set of program quality standards. States also regulate child care programs through licensing systems. Public schools are overseen by local and state regulations and accountability systems.

Studies have found that the quality of many ECE programs is only mediocre, and that infant and toddler programs often do not meet even basic standards for quality. Quality improvement efforts are therefore critically important in order to ensure that all young children have access to programs that can effectively support healthy development and early learning. One approach to improving quality is teacher professional development, described earlier. Another approach is technical assistance provided to early childhood programs to assess areas of strength and areas for improvement, and to support the development and implementation of an improvement plan.

NAEYC program accreditation can be used to make improvements and increase quality. The Boston Public Schools, for example, used the NAEYC accreditation process to improve early education quality, which then resulted in improved academic outcomes among young children. Another approach used by an increasing number of states is a quality rating and improvement system (QRIS). These state systems establish a set of quality standards, a process for assessing ECE program performance on these standards, and they typically provide various kinds of incentives for participation in the QRIS. Incentives include sharing results with consumers and the public, technical assistance services for ECE programs, and/or financial awards or benefits to programs meeting certain thresholds of quality.

The future of ECE offers many opportunities to further develop the profession, and to test new methods for improving the quality of ECE programs. The

last decade has seen heightened national attention to the ECE quality and universal access to ECE for preschoolers. Given the growing linguistic and cultural diversity in the United States, the ECE field is examining ways to strengthen the cultural and linguistic competence of the workforce and to effectively support the healthy growth and development of all young children.

EARLY CHILDHOOD EDUCATION SYSTEMS

Generally, the term *system* is used to describe a set of processes and structures that work together over time to produce a product or set of outcomes. These outcomes could be a physical product, a type of human behavior, or even a biological

process. Systems are pervasive, both occurring in nature and created by humans. On the surface, the concept of a system is well understood; individuals have vast experience interacting with systems—ecosystems, transportation systems, political systems, and economic systems, to name a few. Less understood, however, is the fact that systems are often conceptually and practically complex, and that this complexity affects how the parts of a system function as a whole.

In the field of early childhood education (ECE), there is a complex history of programs and services for young children and families out of which ECE systems have evolved. This entry provides an overview of early childhood systems in the United States, with a particular focus on state-level ECE systems. Beginning with a retrospective look at how ECE systems evolved in the United States, the entry articulates the different types and essential elements of ECE systems that existed in the United States as of 2015. The entry concludes with a prospective view on the future of systems work in early childhood.

Defining an ECE System

If a system can be defined as a set of structures and processes through which a particular set of outcomes can be achieved, an ECE system can be defined as a set of structures and processes through which programs and services for young children and their families are supported. Although ECE systems exist at the federal and local levels, the focus of this discussion is state-level ECE systems, because in most states the entity responsible for creating and/or implementing the policies that govern ECE programs and systems exists at the state level.

Historical Perspective Out of Which Systems Work Evolved

Before one can fully understand ECE systems, it is important to understand the historical, political, and socioeconomic contexts out of which ECE systems have emerged. Historically, the role of providing education and care of young children in

the United States has been relegated to the family. It is not until a child enters primary school that the state provides for universal access to public education services.

The notable exceptions to this paradigm are twofold. First, in times of national crisis, such as World War II and the Great Depression, the government has provided for large-scale access to child care and early education services. The Lanham Act of 1940, which allocated funds to communities affected by World War II, was by 1943 being used to meet the surge in demand for child care as women began working in large numbers in the defense industry. Once this and other crises abated, federal supports were scaled back. Second, the government has intervened in cases where the family needs assistance to meet the needs of their young children. In contrast to the broad governmental intervention outlined in the first example, this type of intervention is targeted to a specific population. Head Start is the archetypal example of this; services are rendered to children and families who need assistance to offset the effects of poverty, ostensibly giving them a “head start” in life.

Operating within the ethos of targeted support to families in need, investments in programs and services for young children and their families living in the United States steadily increased during the late 20th and early 21st centuries. Responding to changes in workforce composition and shifts in economic demand, the federal government, for example, has helped low-income families pay for the high cost of child care through subsidies made available through the Administration for Children and Families’ Child Care and Development Block Grant to states. Simultaneously, many states have been steadily investing in ECE (e.g., publicly funded prekindergarten, home visiting), leveraging the emerging consensus among scholars that high-quality early learning experiences can make a positive difference for young children in school and in later life.

At the same time, as public demand for ECE grows, private foundations and local communities are creating new ECE programs or expanding

existing ones. The result of the influx of myriad initiatives and resources into the field over the past three decades is a patchwork of programs and services either run within the private sector or publicly funded at the local, regional, state, or national level.

Moving From Services to Systems

Despite the inflow of resources into the ECE field, the proliferation of multiple new programs on their own has not necessarily resulted in increased access to programs and services or improved program quality. Rather, as noted ECE systems scholar Sharon Lynn Kagan and others suggest, this rise of programs has resulted in a “non-system” of ECE programs and services. As mentioned previously, services (e.g., publicly funded prekindergarten, Head Start) are often targeted to a specific subset of individuals in need, to the exclusion of many children and families who could otherwise benefit from them. Furthermore, owing to a lack of codified standards to which programs are asked to adhere, low baseline qualifications for the ECE teaching workforce, and a lack of sustained financial and programmatic supports to ECE programs, early learning programs are often low in quality. Missing from these programs and services has been an infrastructure to support the efficient and effective functioning of such programs and services in a systematic and sustainable way. It is from this absence that the press for the development of an ECE system emerged.

Types of ECE Systems and System Elements

Central to understanding what constitutes an ECE system is the fact that among scholars and policy makers in the field, there is no one conceptualization of what an ECE system looks like. In part, this is because the field itself varies greatly. ECE programs themselves are incredibly diverse, services provided to young children and their families vary by state (and sometimes locality), and there is no one standard to which the ECE teaching workforce adheres for professional

preparation. Adding to this conceptual diversity is the fact that the approach to policy making for young children in the United States has been highly episodic, and targeted at different populations and age groups. The result, then, is that ECE systems look different depending on the population they purport to serve.

In their landmark 2012 work on ECE systems, titled *Early Childhood Systems: Transforming Early Learning*, Kagan and Kauerz identify three types of ECE systems: (1) an *early care and education system*, which focuses on the provision of education and care services for children birth through age 5; (2) an *early learning system*, which, in aligning itself with the developmental period defined as early childhood, expands its purview to include children birth through Grade 3; and (3) an *early childhood system*, which focuses on the care and education of children birth through age 8, but also encompasses comprehensive services for young children birth through Grade 3, such as mental and physical health services. These three types of systems offer a framework for bringing coherence to the myriad programs and services that exist within each state. That is to say, these systems attempt to tie together coherently the numerous programs and services for young children, their families, and the ECE workforce that exist in that state. This “tying together” is accomplished by creating specific infrastructural elements from which *all* programs can benefit.

Regardless of which type of system a particular state adopts and what subset of the population it intends to serve, the ideal outcomes achieved via an ECE system are, as Kagan and Gomez note in the 2015 work *Early Childhood Governance: Choices and Consequences*, improved ECE program quality, more equitable access to early childhood programs, and services to children and families that are delivered in a sustainable and systematic way. In order to function and achieve these system-level outcomes, an ECE system must contain seven specific elements, as defined by Kagan and Kauerz in their aforementioned text on ECE systems and advanced again in *Early Childhood Governance: Choices and Consequences*. They are as follows: (1) financing for

ECE programs and services; (2) professional development and workforce supports for ECE professionals; (3) accountability measures to ensure programs meet quality and fiscal benchmarks; (4) outreach to and engagement with families and communities; (5) standards including early learning and development standards, program quality standards, and standards for professional preparation; (6) regulations articulating the minimum requirements for health and safety; and (7) governance structures in place to manage each of the other six elements and the programs and services that these system elements are designed to support.

ECE Systems: Current and Prospective Work

As of mid-2015, no state in the United States had a fully functioning ECE system, though many states do have several of the system elements developed and implemented. All states, for example, do have health and safety regulations for early childhood programs. Most states have early learning and development standards for children ages 3 through 5, and some baseline qualifications for the ECE workforce. The degree to which a state may have developed the other system elements varies greatly.

Recognizing the utility of ECE systems, scholars and policy makers alike have begun to think about how they can support states’ efforts to build ECE systems. The federal government, for instance, has induced states to build ECE systems via the Race to the Top—Early Learning Challenge Grants, which give states significant financial and technical assistance to focus on developing specific system elements. Other organizations, like the BUILD Initiative and the National Center for Children and Families, have supported state system-building work by conducting systems-relevant research, and by creating peer-to-peer networks so that states can share with each other their successes, challenges, and ideas regarding the creation of the seven system elements. Indeed, there is enthusiasm in the field for the benefits that could be incurred as a result of states having fully functioning ECE systems.

Conclusions

Acknowledging the importance of early learning experiences in the first 8 years of life as critical in shaping a child's success in work and life means that the field of ECE is obligated to strive for equitably distributed ECE programs and services that are of the highest quality. The creation of comprehensive, integrated, and coordinated ECE systems is imperative if the field is to meet this obligation. While the field still has a long way to go in developing ECE systems—both conceptually and practically—the notion of focusing on the system (i.e., the infrastructure), alongside investment in ECE programs, holds great potential for achieving the desired ends of quality, equity, and sustainability.

EARLY CHILDHOOD INCLUSION

Early childhood inclusion is the principle that supports the rights of young children with disabilities to be cared for and educated alongside their typically developing peers and to participate in a broad range of activities as full citizens of society. There is widespread policy, research, and societal support for the principle of inclusion. This entry provides information about the legal, research, and values base for early childhood inclusion, an agreed-upon definition and defining features of high-quality early childhood inclusion, and steps to take to ensure that high-quality inclusion is available for all young children with disabilities.

Legal Base

Although inclusion is not specifically defined in law, the principle is supported through legislative mandates related to equal opportunity and basic rights to be educated. Inclusion began in 1954 with the *Brown v. Board of Education* Supreme Court decision and was extended by legislation over the decades (the Americans with Disabilities Act, the Individuals with Disabilities Education Act [IDEA], and Section 504 of the Rehabilitation Act) requiring schools and agencies to provide equal educational opportunities for children with disabilities.

IDEA specifically requires schools to educate children with disabilities ages 3 to 21 in the least restrictive environment and for those ages 0 to 3 promotes providing early intervention services in natural environments. These legislative requirements promote inclusion by addressing the rights of young children with disabilities to receive educational and developmental services and to participate in typical academic and non-academic settings and activities. For example, child care programs cannot discriminate and deny admittance to young

children with disabilities and must make reasonable accommodations for them so they can succeed in that environment, and disability services must make every effort to serve young children with disabilities in community-based and home settings rather than special schools, clinics, or hospitals.

Research Base

Inclusion has been studied for over 30 years. Certain conclusions about its implementation can be made based on that research. These include the following:

- Inclusion has been called many things (e.g., integration, mainstreaming), has been implemented in many different ways, and the extent to which young children are included varies from state to state, community to community. There is little uniformity in what inclusion is or is not and the extent to which young children with disabilities have access to it.
- Multiple factors shape implementation of inclusion. Certain key factors are critical to inclusion being successful. These include research-based instructional strategies (e.g., embedded interventions) being implemented as intended with children with disabilities and strong collaboration among parents, teachers, and specialists in the context of inclusion.
- Inclusion can benefit young children with and without disabilities, and many families view inclusion in a positive light.
- Early childhood professionals may not be adequately prepared in preservice education or supported on the job to implement inclusion. Professional development on inclusion is a critical need for ensuring that high-quality inclusion services and programs are available for young children with disabilities.

Societal and Professional Support

In principle, the concept of inclusion has had broad support in the United States as part of broader societal values related to individual rights to freedom, education, and full citizenship.

However, the lack of a shared understanding about what inclusion means has led to challenges with implementation. The search for a uniform agreed-upon national definition of early childhood inclusion came to fruition in 2009 when the two national early childhood professional organizations, Division for Early Childhood of the Council for Exceptional Children (DEC/CEC) and the National Association for the Education of Young Children (NAEYC), published a joint position statement specifying a definition and key features of high-quality early childhood inclusion. The definition is as follows:

Early childhood inclusion embodies the values, policies, and practices that support the right of every infant and young child and his or her family, regardless of ability, to participate in a broad range of activities and contexts as full members of families, communities, and society. The desired results of inclusive experiences for children with and without disabilities and their families include a sense of belonging and membership, positive social relationships and friendships, and development and learning to reach their full potential. The defining features of inclusion that can be used to identify high quality early childhood programs and services are access, participation, and supports. (DEC/NAEYC, 2009, p. 2)

As stated in the joint position statement, *access* means providing a wide range of inclusive learning opportunities, activities, settings, and environments for young children with disabilities. *Participation* means intentionally making accommodations, modifications, and using a range of strategies and approaches to ensure that young children with disabilities fully participate in play and learning activities with peers and adults. *Supports* refer to the systems-level components that must be in place to undergird the efforts of individuals and organizations providing inclusive services to children and families. These include structures and opportunities for collaboration among professionals and families, professional development on research-based inclusive practices, adequate resources to support high-quality

inclusion, policies supporting inclusion, and research and evaluation to learn more about inclusive strategies and approaches that are effective. More details about the joint position statement and each of these essential features is available at the website of the National Professional Development Center on Inclusion.

Recommendations

The legal, research, and values base for inclusion is strong. To ensure that each and every young child with a disability has access to participate in high-quality inclusive services and that the practitioners who serve those children receive the support they need requires ongoing efforts. What follows are recommendations for leaders, practitioners, and families for achieving that goal.

- Examine program policies (e.g., admissions, service delivery) and mission statements in light of the definition and key features of early childhood inclusion to ensure that children with disabilities and their families feel welcomed by the program, and share these policies with all staff and families to ensure they understand the commitment to inclusion.
- Examine program structures and resource allocation to ensure that staff have the support they need to fully implement high-quality inclusion.
- Provide staff with accessible, affordable, high-quality professional development opportunities to facilitate their acquisition and application of research-based inclusion practices.
- Advocate for federal, state, and community policies, procedures, standards, and systems that support the implementation of high-quality inclusion.
- Participate in and conduct research and evaluation to learn more about inclusive strategies and approaches that are effective in promoting positive and desired child and family outcomes.

EARLY CHILDHOOD RESEARCH AND POLICY LINKAGES

Early childhood research has contributed significantly to the development of public policies to create and expand services for young children and their families. Most recently, research on the neurodevelopment of children during the first 3 years of life has demonstrated how critical early experiences are to children's future development and school success. These early experiences impact the degree to which children form attachments, are curious and interested in the world around them, and develop the ability to communicate, explore,

learn, and play. The importance of early neurodevelopment and the findings from several classic early childhood longitudinal studies have spurred legislation to create programs at the federal and state levels, such as Head Start and Early Head Start, early childhood special education, and state prekindergartens.

The translation of the research findings to actual program implementation is linked through the legislative process and policy development. Legislation identifies the services and the appropriations to fund them. Regulations then are written to provide guidance on issues such as what the services are, who will receive services, and who the providers of the services may be. Policy decisions then make explicit the conditions under which new services are developed, implemented, funded, and evaluated. In some situations, research findings provide clear guidance for what policies should be written and enacted. In other cases, policies are implemented before the research evidence is fully available, and subsequent research is used to support and sustain the continuation of policies.

This entry presents the links between research and policy in the expansion of services for young children considered at risk for later school problems, because of either poverty or disabilities. The influence of values and public advocacy on research and policy also is addressed as components within an ongoing cycle of research and policy development.

Policy Spurs Research: Head Start

In 1964, the Head Start program was created as part of the War on Poverty under the Economic Improvement Act. The goal of Head Start was to break the cycle of poverty by providing early compensatory education to young children prior to formal schooling. Head Start also included the provision of health, dental, and nutritional services to improve the wellness of children in poverty.

In many ways, Head Start was initiated as a promise to improve educational and economic outcomes for poor children and as a statement that young children are valued. It was sustained over time because of research findings that demonstrated unequivocally that early education was a

sound investment based on long-term outcomes for the participants. More than 50 years later, Head Start serves almost 1 million children each year from birth to age 5. The research to support the continuation of policies for compensatory early childhood programs, such as Head Start, is well established, as are the values and advocacy for maintaining these programs.

The evidence most frequently cited to support the continuation of Head Start has come from two major research studies, initiated during the early years of Head Start. In 1962, the High/Scope Perry Preschool Project enrolled 123 African American children living in poverty. Half of the preschool children were randomly assigned to a high-quality preschool and the other half received no services. Those who attended 2 years of preschool consistently scored higher on language and intelligence tests up to second grade. Later, when tested at ages 9, 10, and 14, the preschool group also scored significantly higher than its peer group on school achievement tests. Members of the preschool-educated group were more likely to graduate from high school, and at follow-up checks made at ages 27 and 40, they were more likely to be employed than the peer group who received no preschool.

Similar gains were noted in a second study, the Carolina Abecedarian Project, in which 111 infants, living in poverty, were assigned randomly to one of two programs through kindergarten entry. Both groups received full-day, year-round child care, but one group also received an enriched curriculum. The children who received the enriched curriculum showed greater gains than their peers, as measured by higher IQ scores at 36 and 54 months. Gains in performance were noted at follow-up assessments conducted when the children were 15 and 21 years of age. As in the first study, long-term follow-up measures showed better life outcomes.

Despite evidence in support of preschool for children in poverty, Head Start is not available for all eligible children. The program is funded in local communities through a competitive grant application process that is managed federally through regional offices. An estimated half of all children who could benefit from Head Start are able to

enroll because of the limited number of programs and enrollment slots. Federal policy has not yet responded to the benefits of universal preschool for children in poverty, although the research findings are clear. Increasing access to Head Start or other prekindergarten programs will require public advocacy, the efforts of communities to press for greater spending, or expanded legislation, if all children are to be served. Efforts in most states to fund additional prekindergarten programs eventually may fill this program gap.

Policy Follows Research: Services for Preschoolers With Disabilities

An accumulating body of research on the effectiveness of early intervention for children with developmental delays or disabilities led to the 1986 reauthorization of the Individuals with Disabilities Education Act (IDEA). This legislation changed the age when school-age services for children with disabilities became available from age 6 to age 3 and provided states with incentives to develop a service system for infants and toddlers with disabilities and their families. For the first time, children with disabilities could receive services from birth through 21 if they met their state's eligibility requirements.

Research findings and advocacy efforts combined to create this expansion of services to very young children. Between 1968 and 1986, the Office of Special Education Programs in the U.S. Department of Education funded hundreds of research and demonstration projects as well as personnel development programs to assess the extent to which services could be developed and implemented to improve the quality of life and enhance learning of young children with disabilities. The preponderance of research and demonstration programs provided evidence that preschool services for young children with disabilities provided educational and economic benefits. Findings from demonstration projects also provided a range of models for providing services, including serving children in community child care programs, Head Start, self-contained public school special education classes, home visiting, or a combination of services.

Federal regulations developed for the IDEA legislation required that preschool-age children be served in "the least restrictive environment" (LRE), which is interpreted as the opportunity to be educated with peers without disabilities to the greatest extent possible. The LRE policy allows the addition of supports in the form of adaptations and accommodations as well as paraprofessional aides as needed. As a result of the expansion of services for preschool-age children with disabilities and the LRE policy, almost 65% of children with disabilities attend regular early childhood programs for some of their school day. In 2012, 6% of all children ages 3 to 5 received early childhood special education services. Their increasing presence in regular early childhood programs has produced both research on effective strategies for inclusion as well as widespread discussion among professional groups on how best to support children with disabilities in inclusive programs.

Research and Values Expand Policy: Inclusion

The National Association for the Education of Young Children (NAEYC) and the Division for Early Childhood of the Council for Exceptional Children (DEC/CEC) collaborated on a joint policy statement to guide their members in the field of early childhood education on inclusion. This policy statement builds on research as well as federal policy. It is values based in that it supports the rights of every child and family, without regard to ability, to participate as full members of their communities. Developed by the two primary early childhood organizations in the country, it advocates for the inclusion of all children.

Three features define the policy of inclusion: access, participation, and supports. Access refers to ensuring that all children can be engaged through the use of universal design and, as needed, assistive technology and augmentative communication devices. Universal design refers to creating curriculum that supports multiple ways to represent a concept, to express knowledge of the concept, and to engage in the learning process. It recognizes that individual learning is unique and is designed to

reduce barriers to representing, expressing, or engaging in learning. The concept is consistent with teaching practices that are flexible and address the developmental age and abilities of each child. Participation refers to the active involvement of children in the curriculum and can be supported in a variety of ways, including modifying or simplifying activities, having peers help one another, or providing various levels of instructional support.

Extensive research has provided strategies on how to support social interactions among young children with and without disabilities. Likewise, much research is available on varying levels of instructional supports, including cuing, prompting, modeling, and hand over hand. The policy statement also addresses the system-wide supports that teachers, staff, and administrators need to address the social and learning needs of all children. Examples include opportunities for professional development, for collaborative planning, and for consultation.

Research Expands State Policy

As of 2015, 44 states have funded preschool programs, enrolling as many as 1.3 million children. The majority of children served are age 4, and the intent of the programs is to prepare them for their next year of formal schooling (kindergarten). Enrollment varies widely across states, however. Federal policy and federal funds are not the drivers of these programs; instead, states have passed legislation to appropriate funds to support the expansion of services. Some states share the cost of prekindergarten through a formula of state and local funds. The impact of research on gains made in early childhood programs is a major influence in state policy establishing early childhood services.

The extent to which states are willing and able to identify funds for the prekindergarten programs impacts the number and percentage of children served. In most states, eligibility for services is related to income level or specific risk factors (e.g., English language learners, single-parent homes). In a few states, prekindergarten programs and local Head Start programs collaborate in the delivery of services. In other states, the programs operate independently.

A point of debate is the extent to which funding is adequate to ensure that programs are high in quality and staffed with licensed teachers. One way to estimate the quality of the programs is the use of benchmarks created by the National Institute of Early Education Research (NIEER). It identified 10 quality standards or benchmarks that are well supported by the research literature as indicators of minimum criteria for effective, high-quality programs. Examples include class size and teacher ratio, use of early learning standards, in-service training for staff, and specialized training in early childhood. As of 2014, all participating states met the benchmark of adopting early learning standards to guide their curriculum. However, only five states met all 10 benchmarks, and another 15 met at least eight benchmarks.

Policy makers have noted that state-funded prekindergarten programs are at a crossroads. Funding has not increased substantially in recent years. Although legislation has been proposed for a federal–state partnership to fund preschool for all low- and moderate-income 4-year-old children, this had not been enacted into law as of mid-2015. The commitment of a majority of states to provide some level of early childhood education to children living in poverty, however, underscores the growing acknowledgment that early schooling makes a difference in long-term educational outcomes.

EARLY CHILDHOOD SCIENCE EXPERIENCES

Young children are biologically equipped to actively explore and learn about their world. From infancy onward, evolving brain structures enable sensory attention and trigger curiosity about their environment. Curiosity events recruit neurochemicals that prompt emotional responses and promote memory—the deepest roots of learning. Each new learning experience changes and enlarges neural pathways in the brain to allow for more learning. When intriguing, developmentally appropriate experiences are provided to help young children enjoy investigating their world, and guidance is offered to make conceptual meaning of their discoveries, the curiosity-motivated capacity for further learning is nourished. Supporting this intrinsic reaching out for knowledge is the purpose for early childhood science experiences. This entry traces the rise of interest in early childhood science experiences as pedagogy, and reports on research on the underlying cognition and the beneficial outcomes of those learning opportunities. It then describes two differing perspectives on providing appropriate early childhood

science investigations, and points to the trending use of the environment as a valued context for early childhood science experiences.

History

The progenitor of early childhood science experiences was Friedrich Froebel. His pioneering 1840 kindergarten established play-based learning as children's eager way of discovering how things work. Froebel promoted outdoor play and gardening for learning in and about nature. He developed holistic activities using many learning pathways, and designed learning manipulatives to help children understand mathematic relationships. The principles and practices that he originated continue to influence early education worldwide.

Nevertheless, the prevailing belief among other educators continued to hold that young children lacked the intellectual capacity to learn much of academic significance in the years before school. Seminal research in cognitive development by Jean Piaget in late 1950 spurred wide interest in how and when young children can do abstract reasoning about phenomena. By 1970, research findings challenged Piaget's age/stage-limited theories that set 8 years of age as the beginning of abstract thinking. Researchers found, instead, that children are able to reason about things they experience much earlier, and with greater capability than Piaget had proposed.

In the same period an education philosopher, David Hawkins, founded a Colorado preschool focused on developing learning through open-ended, in-depth, long-term projects to answer questions children raise. Children and teachers collaborate to plan and carry out active investigations in the school, community, and in nature. Hawkins's writing about his project approach and his leadership in public education policy brought early childhood science experiences into the education mainstream. In 2012, a National Science Teachers Association position paper, *Early Childhood Science Education*, officially acknowledged that early fostering of children's

curiosity and pleasure in exploring their familiar world lies the foundation for the K–12 science learning ahead.

Research

Research foundational to early childhood science experiences shows

- emotion and cognition are inseparable, critical components of learning;
- the emotional response to curiosity enhances memory and prompts further curiosity;
- young children understand more from science experiences with tangible materials than from virtual manipulatives; and
- using the environment as an integrating context for learning significantly raises children's academic achievement.

Teaching Approaches

Meaningful science experiences for young children build on the emotional underpinnings of their innate curiosity, their concerns about their everyday world, and their pleasure in exploring their world. Direct, didactic teaching *about* science is antithetical to experiencing science firsthand. The range of valid approaches to providing firsthand experiences tend to fall in varying degrees into two categories:

Child-Initiated Experiences. Constructivist science approaches provide younger children with appropriate materials such as sand and water, simple equipment, and sufficient time for repeated, spontaneous explorations while teachers offer *indirect* guidance to encourage children's thinking and talking about their discoveries with other children. According to constructivist theory, children's active engagement enables building new knowledge upon their existing knowledge. The teacher participates more actively in guiding older children, introducing measurement and observation tools, conducting meaningful dialogues with children, scaffolding to stretch their reasoning, and indirectly leading them toward broad concepts such as *change*

through growth and *form and function*. Related math, writing, and art extend the learning.

Teacher-Initiated Experiences. Carefully chosen, emotionally engaging science experiences are organized and guided by teachers to lead children toward conceptual knowledge. Investigations are introduced by raising questions relevant to children's immediate experience. Children contribute what they already know, and raise further questions in class discussions. Active, firsthand explorations and observations of familiar materials and events are then led by *indirect* probes and questions to help children find concept-building answers. Follow-up discussions process what took place in the investigations, and consider connections with previous conceptual learning.

The concepts are reinforced by integrating them across other disciplines and aspects of the curriculum, including math, literature, art, music, creative movement, creative thinking, and dramatic play. Howard Gardner points out that confirming a concept in many contexts leads to deeper understanding, and better reaches the varied learning orientations among children. Integrating science experiences with other aspects of the curriculum and making connections among concepts align with the "crosscutting concepts" dimension of the Next Generation Science Standards for Grades K–12, while developing concept learning builds foundations toward understanding the "core ideas" dimension of the Next Generation Science Standards.

The Outdoors as a Context for Science Experiences

There is a rapidly growing trend in this country and abroad to develop natural school environments and school gardens so that the benefits of outdoor play and learning in nature can enhance the whole preschool and elementary school child. This early appreciation of nature preserves children's sense of wonder and sets them on a path to future responsible stewardship of the earth—worthy and hopeful science experiences.

EARLY CHILDHOOD SPECIAL EDUCATION

Early childhood special education, often referred to as ECSE, is a broad term used to define programs and services for children 3 to 5 years old who have a diagnosed disability or a developmental delay. The Education for All Handicapped Children Act of 1975, which was amended in 1986 to add preschool children, evolved into the Individuals with Disabilities Education Act (IDEA) of 2004 and now has two parts to ensure that very young children receive services and interventions as do their school-age peers. Part B of IDEA refers to services and programs that support children between the ages of 3 to 21 years old and are referred to as school-age programs. Programs specifically for children 3 to 5 years of age under Part B (Subpart H) are classified as early childhood special education, or ECSE. Part C of IDEA was added later in 1996 and is for educational programs for infants and toddlers, birth to age 3, and is classified as early intervention, or EI. Table 1 compares Part B services and Part C services for IDEA. ECSE, Part B, commonly referred to as preschool services, is a blend of early childhood education best practices, child development, and special education services.

There are many ways to qualify for ECSE services. First, if a child has received early intervention services he or she will be transitioned to ECSE when he or she turns 3 years of age. If transitioning from EI, the individual family service plan (IFSP), a family-centered and state-run program created for EI, will no longer be in place. The school district will now be responsible, and an individualized education program (IEP) will be written.

Although some children receive a firm diagnosis for conditions such as deafness and Down syndrome between birth and age 3 because of newborn hearing screenings and genetic testing, other children receive early intervention services because of developmental delays or being at risk for developmental delays. However, a child will no longer qualify for ECSE services without a specific

Table 1 IDEA Part B and Part C Comparison*

	<i>IDEA Part B—Early Childhood Special Education (ECSE)</i>	<i>IDEA Part C—Early Intervention (EI)</i>
Age range	Part B is for those 3 to 21 years of age; ECSE is specifically for children 3 to 5 years old	Birth to age 3 years
Financially responsible for services and coordination	School districts	States
Environments	Preschool, prekindergarten, special education classrooms, child care centers, and kindergartens	Natural setting for the child: home or child care
Central focus	The child	The family and child
Binding document created	Individualized education program (IEP)	Individualized family service plan (IFSP)
Document and plan reviewed	Once a year	Every 6 months

diagnosis, confirmed health impairment, or documented delay. If a child did not receive EI services, he or she may still qualify for ECSE. There are multiple pathways that allow children to be eligible for services including to be referred for ECSE through school staff, physicians, and child find agencies as well as through the tiered system of response to intervention (RTI).

Once a child qualifies for ECSE, an IEP will be written to include services, interventions, and environments and it must be reviewed each year. Typically for children 3 to 5 years of age, the educational environments include preschools for typically developing children, special education preschools, prekindergartens, and kindergartens in both public and private settings, as well as child care centers and other community-based settings. Service providers include speech and language therapists, occupational therapists, physical therapists, teachers of the deaf, teachers of the visually impaired, mobility specialists, special education teachers, advocates, social workers, behavior specialists, psychologists, and nutrition

counselors. The coordination of services for Part B is maintained through the child's local school district. Additionally, the early childhood education teacher and classroom aides become part of the IEP team for ECSE. Part B ECSE services are often met in inclusive settings or the least restrictive environment (LRE), with interventions embedded in play, caregiving, and daily routines.

According to a 2009 position statement from the Division for Early Childhood (DEC) and the National Association for the Education of Young Children (NAEYC), there are three main areas to consider for early childhood special education: access, participation, and supports. Barriers to learning are to be avoided so that children with and without delays are educated together. This involves giving children equal access not only to toys and the classroom environment but also to content, language, peers, and assessments. This access is more than allowing a child with a special need into a general education preschool and more than just attending or being present in the classroom. The child with a special need must also have access

to and be a fully participating member of the classroom community to gain the most benefit from the early childhood classroom. To have access and ensure participation, supports, scaffolds, and other interventions are provided to allow the child with a special need to fully benefit in an early childhood special education setting.

To ensure that all children have access, the concept of universal design for learning (UDL) is commonly used. In classrooms designed according to UDL principles, content is shared or represented in various ways to meet the needs of all learners. The child has multiple ways to be engaged with content and peers. Finally, the child, regardless of his or her disability, must be able to express his or her understanding and knowledge without barriers. Understanding by Design (UbD) as well as differentiated instruction (DI) play important roles as classrooms, activities, and curricula are designed to ensure success for all learners. UbD ensures goals and outcomes are created to best meet each individual child's needs while ensuring progress. Modifications, adaptations, and differentiation are provided to meet each child's unique pathway to those goals. This includes the environment as well as the curriculum, teaching strategies, interventions, assessment, and instructional practices used.

Collaboration among early childhood professionals, special education teachers, specialists, therapists, and families is essential and a necessary part of a successful ECSE program. Families remain an important partner in ECSE, just as they are in early childhood education and early intervention. Families are included in IEP development and are considered a main resource for providing information regarding their child.

As professionals across specialty areas (i.e., special education, speech, physical therapy, early childhood) work together, there are often different philosophies represented. Each professional, based on his or her expertise, tries to best meet the needs of the child with a disability. There can be conflicts with what is seen as developmentally appropriate practice (DAP) for early childhood education when providing services that include therapy, hand-over-hand guidance in helping a child with

tasks, and other one-on-one adult-led sessions. However, DAP and special education frameworks have many common overlaps including individualization, family and cultural focus, following the child's interests and strengths, and scaffolding children's learning to document growth. DAP can be the basis or foundation of the ECSE classroom and does not require any aspect of special education services to be changed or adjusted. However, this can only happen if all professionals involved in ECSE programs, regardless of area of specialization, are familiar with child development and early childhood best practices and agree to build therapy and interventions in developmentally appropriate ways. Continued professional development for all involved as well as time for consultation and collaboration is essential for ECSE services to be successful.

EARLY CHILDHOOD TEACHER EDUCATION

There are certain issues of importance for all students in the field of early childhood education. Those training to be early childhood care providers and teachers will work with society's youngest members at a critical time period of their lives. Work in this field is often seen as nothing more than playing with or babysitting infants and young children. However, students of early childhood education need to recognize the rich history and wide-ranging research supporting the field. Students also need to understand the importance and long-lasting effects of this significant work in a young child's life—as well as in the lives of a child's family.

Working in the varying environments serving families with young children requires solid education with guided practical experiences. This education includes knowledge of the 200-plus-year history of early pioneers in the field as well as knowledge of the recent theories guiding the knowledge of child development and early childhood education. How are best practices understood? Why is it vital for the early childhood workforce to strive for cultural competence? And how do family systems models help inform the practice? Highlighting a number of important issues in early childhood educator training, this entry brings together critical aspects running through the field of early childhood teacher education.

Roots of Child Development

The roots of early childhood education as a field of study cover a period of 200 years from England, Germany, Italy, Switzerland, and the United States. Significant pioneers offer multiple contributions to the field, including John Comenius and John Locke, who were both interested in parent interactions with children, and what it meant to be individuals and citizens in the 17th century. In the 18th century, Johann Oberlin and Johann Pestalozzi organized schools as one way to help prevent poverty and work toward social justice.

Robert Owen's work was influenced by Pestalozzi's idea of introducing schools for infants, reducing the use of children as laborers. Owen also started schools in both Europe and the United States for children of working parents. Educators Margarethe Schurz and Elizabeth Peabody, who had both studied with Friedrich Froebel, helped extend Froebel's kindergartens in the late 1800s in the United States. And Maria Montessori, one of Italy's first female physicians, developed schools for children of the poor, introduced child-sized furniture and materials in school environments, and helped identify strengths in all learners—both able-bodied children and those considered disabled in the early 1900s. These are just some of the men and women whose pioneering work contribute to our understandings of current societal views related to infancy, development, and other issues of early childhood education, according to Harry Morgan, in *Early Childhood Education: History, Theory, and Practice*.

The work of modern psychologists, discussed below, has also influenced the field of early childhood. Additional influence came from a group known as the Transcendentalists, including Horace Mann, Ralph Waldo Emerson, Nathaniel Hawthorne, and Henry David Thoreau. The Transcendentalists were interested in the education of young children and believed people were at their best when they were self-reliant and independent. Educators coming out of this group believed in a child's ability to self-direct and capacity for self-understanding, both principles of constructivism discussed later in this entry. The Transcendentalists also argued for various freedoms—intellectual, moral, and inquiry, as well as the following: “belief in human virtue and respect for all peoples [are] essential human values” (Morgan, 2011, p. 25).

Defining Child Development and the Field of Early Childhood Education

In addition to looking at historical roots of early childhood education, it is equally important to consider how child development is defined. Child development considers those processes in which a child matures in domains—physical, cognitive,

and emotional—as he or she ages. This development includes the acquisition of skills, the ability to manipulate materials, working to achieve goals, and gaining an understanding of how to re-create actions or behaviors. Early childhood education focusing on the span from birth to 8 years is considered the most vulnerable and crucial time in a person's life. It is a time of incredible brain growth, thus laying the foundation for future learning and development. In the United States, early childhood education relates to the development and learning of young children, typically before the start of mandated education. It is important that the period of early education is not viewed as a time when young children are “taught” to develop and learn. Rather, a clear tenet of early childhood education is that through their own development children will grow, learn, and acquire abilities through their interactions with the world.

Early childhood education programs are referred to by many names, including infant and toddler day care or child care, nursery school, preschool, prekindergarten, and the early elementary years—typically kindergarten through third grade. Early childhood education and care can also be delivered in multiple settings: home or center based, and located in urban, suburban, and rural communities. Programs may be offered part-time or part-year, while others offer full-day, year-round services. Programs can also be run privately, as either non-profit or for profit; they may be operated within local school systems or separately as state- or federally funded programs. Early childhood education programs often focus on guiding children's learning through play, with various activities and experiences intended to encourage and support developmental changes as children age.

Best Education Practices Defined

Best practices in development and learning in early childhood education concern what and how an environment or setting can best support a child's development. Looking at growth from the perspective of developmental goals (age, domains) allows parents, caregivers, and teachers to determine the

best ways to provide support. Included within these guidelines are expected abilities for children within certain age ranges or time points.

In addition to the early childhood pioneers, major influences on what is understood as best practices currently stems from 20th century influences from the field of psychology. This includes works of Sigmund Freud, John Dewey, Lev Vygotsky, Jean Piaget, and Erik Erikson, according to Morgan (2011). Through the lenses of these theorists, we can note differences between early childhood education and public education. Historically, prior to 1970 “college education and training for early childhood teachers included an early childhood framework, foundations of sociology, and psychology of early childhood and practice based on 100 year old childhood tradition” (Morgan, 2011, p. 97). This earlier training focused on “how children learn”; however, early childhood teachers trained after 1980 were educated in programs that combined early childhood education along with elementary education teacher training. The training focus changed from how children learn to “what children should be taught” (Morgan, 2011, p. 97). Blended training programs, including elementary, middle, and high school teachers, ignored the significant traditions of early childhood education, something that is currently a struggle within the field, states Morgan.

Following the more recent formula of “what children should be taught” eliminates the early childhood development foundations common to theories of Freud, Piaget, Montessori, and Erikson. These foundational ideas include the notion that individuals pass through phases where a child's growth and development move ahead in chronological, age-sensitive stages and that by missing some experiences at certain time points development discontinues. Additional to this framework is the idea that development is influenced by the multiple relationships children have including those between peers, teachers, parents, and other significant adults and by the environments in which a child lives. The “what children should be taught” philosophy denies both children and teachers the opportunity to discover “how children learn” (Morgan, 2011).

Other aspects involving the history of the field of early childhood education and influences on best practices in education include issues of human rights—that all children have these rights and that these human rights have been ignored toward certain populations, in particular Native American and African American children. Additional historical events influencing early childhood education include the freedom movement to end slavery, the women’s rights movement, social concerns including child labor practices, care and placement of orphans, general interest in the education of young children, and the view that the practice of early education is also a human service. Even now many adults remain unaware of the education needs for society’s youngest members. A common question around educating children aged 6 years and under remains, “Who needs special training to teach ‘the little ones’?” (Morgan, 2011, p. xi).

National Association for the Education of Young Children

The leading organization focusing on early childhood education, the National Association for the Education of Young Children (NAEYC), guides the field in defining best practices. A major emphasis of the organization is to disseminate information that outlines practices promoting optimal learning and development in young children. The following list, while comprehensive, is not all-inclusive and is a rendering of NAEYC’s (2009) best practices for making decisions and meeting the needs of young children:

- Development and learning follow sequential patterns and build on previous skills:
 - Can occur at varying and uneven rates in individual children;
 - Occur with interactions between maturation and experience;
 - Happen best in children within secure and consistent relationships among adults and positive peers;
 - Happen and are influenced by social and cultural contexts;

- Progress when children are challenged just beyond their ability and when they have multiple opportunities to practice new skills.
- The physical, social, emotional, and cognitive domains are important and interrelated with development in one area influencing other areas.
- Early experiences can have profound effects on development and learning, and there are “optimal periods” for some categories of development to occur.
- Development evolves from less complex to more complex.
- Children learn in multiple ways, responding to various strategies and interactions.
